It will be unnecessary to enter here into the details of the scheme; suffice it to say that any funds will be invested in the names of five trustees, and that the income derived from them will be paid over to a general committee consisting of these trustees and three representatives of the College of Physicians (the president and two censors), three representatives of the College of Surgeons (the president and two vice-presidents), the members of the laboratories committee of the Royal Colleges of Physicians and Surgeons, and one member, to be nominated by the Local Government Board. The general committee will have control of the income of the fund, but concerning the exact method of spending it they will take counsel with an advisory board, which will consist of the laboratories committee of the Royal Colleges and other members chosen in equal numbers by each of the Royal Colleges. It is estimated that the sum of 100,000*l.* will be required for the above purpose. At the present time, funds are conspicuous by their absence.

To the lay mind the term cancer does not imply a well-marked entity; the word is, in fact, occasionally used as synonymous with tumour, meaning, roughly, a swelling or growth where a swelling or growth ought not to be. To the medical mind the term cancer means a special form of tumour which is characterised microscopically by its structure and clinically by its method of growth. This latter is of two kinds, local and general. The local growth consists of an infiltration of the adjacent tissues, the general growth of a dissemination of the particles of the disease which produce growths, conforming in type to the original tumour, in parts of the body more or less remote from the seat of the primary affection. So far as concerns their minute structure, however, tumours growing in the above manner are not all, from the histological standpoint, cancers or carcinomatous. This term has been made by morbid histologists conventionally to designate a definite variety of tumours growing in the above-stated "malignant" manner, viz. those the microscopic structure of which is of the epiblastic or epithelial type. This classification is rendered necessary by the fact that there exists another class of tumours equally malignant, but the minute structure of which is of the connective-tissue or mesoblastic type. These tumours

are termed "sarcomata," a term as meaningless as its congener, carcinoma. We have, then, speaking roughly, two great classes of tumours, the so-called innocent tumours, or those which grow slowly and locally, and the malignant tumours, which grow rapidly and become disseminated all over the body. This latter group, although consisting of two classes, the carcinomata and sarcomata, are generally designated "cancers," and are, no doubt, although, so far as we can ascertain, no specific information is to hand upon the subject, to be the objects of the proposed research.

As very often happens when facts of unmistakable significance are wanting, theories are abundant. This is certainly true of cancer. It must at once be admitted of the theories with regard to the causation of cancer, that although they have no doubt been of great value in assisting what may be termed the crystallisation of histological results, they have, tending as they do rather to express one enigma in terms of another, been of little value from the absolute practical standpoint. Six distinct theories have been put forward concerning the pathogenesis of cancerous growths. Perhaps one of the most generally accepted is Prof. Virchow's theory that these growths are caused by injury or chronic mechanical irritation. There can be no doubt that cancerous growths very frequently affect the parts of the body, either external or internal, which are most frequently subjected to some kind of irritation. Cancer of the tongue in clay-pipe smokers or in the subjects of rough and uneven teeth, cancer of the scrotum in chimney sweeps, due to chronic irritation of the part by soot, &c., cancer of the breast, of the arms in paraffin and tar workers, of the two ends of the stomach, especially apparent in individuals who masticate imperfectly, can all be cited as showing the predilection of cancerous growths to parts of the body exposed to constant or intermittent irritation. Perhaps of all the numerous common factors in cases of cancer, chronic irritation is the most constant. It cannot, however, be regarded as a universal or even adequate explanation of the disease, for, as Cohnheim has pointed out, in 86 per cent. of all the cases irritation apparently plays no part. Prof. Cohnheim regards cancerous growths as being due to the abnormal proliferation of embryonic remnants. He assumes that in the development of the individual from the embryo, more cells are produced than are required for the building up of the organ concerned. There thus remains an embryonic cellular remnant. These embryonic cells remain always possessed of one characteristic of this variety of cell, viz. an unlimited capacity for proliferation. These remnants may remain quiescent, and then nothing more is heard of them; they may, however, under the influence of certain conditions, assume active growth, and may thus constitute malignant tumours. There can be no doubt that this theory explains many of the features of cancerous growths, and is greatly supported by the fact that, speaking generally, new growths are prone to occur in parts of the body which are the seats of complicated embryonic development. We have, however, some actual knowledge of embryonic remnants in the so-called epithelial pearls which are fairly frequently found in the tonsils, and it must be admitted that these organs are rarely the seats of malignant growths. Further, in Cohnheim's theory the actual cause which stimulates the growth of the embryonic remnant is not defined except in the most general terms, viz. as a condition of malnutrition of the surrounding tissue.

The obvious similarity between malignant growths and the so-called infective granulomata has led many observers to the view that the former disease must, like the latter, have a parasitic origin. The analogy between these two classes of affection is perhaps the greatest when we take tuberculosis as the type of the infective malady. Tuberculosis at first local, confined, for instance, to a given part of one organ, produces secondary infection in the adjacent lymphatic glands by means of the lymphatics, and subsequently from these tubercular material may gain entrance into the general circulation, and being carried by it hither and thither may become implanted in the most remotely situated organs and produce tuberculosis of them. In the case of cancer there is, too, always a primary focus which is strictly local, and in this case also the lymphatic vessels carry the carcinomatous material to the adjacent glands and from them either by means of the general lymphatic system or the general circulation, carcinoma of remote organs may ensue. When we come, however, to examine this analogy, we find that it is more apparent than real. Tuberculosis can readily be conveyed from animal to animal; this certainly is not the case with cancer. It is true that examples of what may be termed the auto-inoculation of cancer in man are not uncommon; for instance, in the case of adjacent parts of the body, cancer of the one may spread to the other; this probably simply means that the cancerous tissue of the one organ becomes ingrafted upon the other. This condition is often referred to as "contact cancer." Ebert has collected twenty-three such cases. The actual infectivity of cancer, using this term in the ordinary sense, is at present doubtful, although several instances are recorded of what may perhaps best be expressed by the French term, "cancer a deux." Nineteen such cases are given by Behla; in most instances the persons affected were man and wife. Some instances are also on record of surgeons inoculating themselves accidentally with cancer from the cancers of patients upon whom they were operating.

The similarity between malignant disease and tuberculosis has led numerous investigators to seek for an organism which would bear the same causative relation to cancer as the tubercle bacillus does to tuberculosis. Carcinomata have received more attention at the hands of these investigators than sarcomata. Into the details of these most interesting researches the space at our command forbids us to enter. The main point of difference between the adherents of the parasitic theory of the origin of cancer and their opponents centres upon the significance of certain undoubted microscopic appearances, chiefly of the growing portions, of cancerous growths. Some observers maintain that these microscopical appearances represent an organism of a protozoic type, others regard them as due to degeneration of the cancer cells. The majority, however, of microscopists do not regard the presence of a parasite in cancerous growths as proved. In the case of sarcomata, the parasite is supposed to be, not of animal, but of vegetable origin, probably a torula.

If we turn from the study of the hypothetical cancer parasite to a consideration of the influence of general climatic conditions upon the incidence of cancer, we shall be treading upon more certain ground. The existence of so-called "cancer houses" seems to rest upon very strong evidence. In one instance, six persons within twenty-six years died of cancer in two houses that were under one roof and had a common drainage and water-supply. The inhabitants affected were for the most part unrelated to each other. So intimate appears to be the connection between the existence of cancerous disease and locality that so-called "cancer fields" have been described. These are found in "sheltered and low-lying vales traversed by fully formed and seasonably flooded rivers and composed of the more recent argillaceous formations." Districts, on the other hand, which possess the lowest cancer death rate are generally more or less elevated areas composed of the oldest rocks, especially limestone. The difference between the death rates from cancer in different regions in north Germany

is very marked. In certain neighbourhoods cancerous disease is responsible for one in every hundred deaths, whereas in others one in every thirty-three deaths is due to this cause.

Concerning the—from the public standpoint—most interesting question whether or not cancer is on the increase, there seems to be some difficulty in giving an unequivocal answer. That the mortality statistics show an increase is certain, but increased longevity and increased accuracy of diagnosis are disturbing factors in the drawing of inferences and have led many statisticians to regard this increase as more apparent than real. So far as the United Kingdom is concerned, the class of cancerous disease showing the most marked increase is that of the digestive organs, and this has led to the formulation of hypotheses with regard to the relation between the increase of meat-eating and the increase of cancer. The greatest note of alarm with regard to the future of cancer comes from America. It is estimated that in Buffalo during the last fifty years the death rate from cancer has increased five-fold, and that if this increment is maintained, at no very distant date this disease will be responsible for more deaths than tuberculosis, typhoid fever and small-pox all put together.

From the above paragraphs, which must be regarded rather in the sense of jottings of facts, the interest and the importance of this subject will be evident. It seems, further, that the mere microscopic examination of malignant growths has already yielded up to the observer almost all the information it can do, and that it is in the direction of pathological experiment that new and important truths should be sought for, and will probably be found. With the history of the recent progress of the treatment of zymotic diseases before us, doubtless the factors possibly concerned in cancer immunity will not escape the attention of investigators. It is sincerely to be hoped that the public will respond liberally to the call which is being made upon them for funds to defray the expenses necessarily required for an investigation at once so time-consuming and so important.

F. W. TUNNICLIFFE.

THE OWENS COLLEGE JUBILEE.

THE series of functions at the Owens College, Manchester, last week, in celebration of the jubilee of the foundation of the College, was carried out with complete success. Prof. S. Hickson was master of the ceremonies, and to him, assisted doubtless by the harmonious cooperation of many others, the greatest credit is due.

The programme on March 12 commenced with the opening of the beautiful Whitworth Hall by the Prince of Wales. The Duke of Devonshire, as president of the College, eulogised the high aims and ideals of John Owens, the founder, in eloquent terms. The Prince of Wales urged on the citizens of Manchester not to be content with the magnificent results of the past liberality of such benefactors as Owens, Beyer, Christie, and Whitworth, but to follow them in liberal support and extension of the College. He pointed out that "the work of an institution of this nature must continually expand; and it must not be forgotten that its material resources must also expand as the work grows." He appealed most forcibly to the generous municipal life and patriotism to enable the College "to keep abreast of the ever-growing demands of modern life."

Sir Richard Jebb and Principal Rücker delivered admirable addresses upon the influence which the College has exerted upon progress in literature and science. The ceremony showed convincingly that the Whitworth Hall justified its dignified beauty of design, by conveniences of access and arrangement and most favourable acoustic qualities. The conversazione in the evening afforded the foreign delegates an opportunity of seeing the Manchester Museum, the whole of the Arts and Science Departments, and the new Christie Library opened four years ago.

On March 13 the actual jubilee celebration was held. Nearly one hundred delegates from academies, universities, colleges and learned societies at home and abroad came forward to present the congratulations entrusted to them and to receive the grip of greeting from the president of the College. The principal proposed the vote of thanks to the delegates, and dwelt on the regretted absence from their number, through illness, of his predecessor, Dr. Adolphus Ward, master of Peterhouse, and of Sir Henry Roscoe, to whom the College is deeply indebted in every way. Prof. Harold Dixon, in seconding the motion, confined himself to the followers of his own science, chemistry, and its sister, physics, and noted with pride the attainments of such as were present as delegates.

Earl Spencer, Chancellor of the Victoria University, then took the chair and admitted the distinguished recipients of honorary degrees. The public orators were the principal. Profs. Wilkins, Schuster, Young, Tout, and Lamb, and Dr. Hiles. Prof. Schuster's presentations were notable for their epigrammatic terseness and point; we may cite his presentation of Dr. Glaisher: "His mind was raised to infinite heights by his mathematical genius; it was brought back to earth by his love of the stars."

An informal "physics colloquium" in the laboratory afforded Prof. Becquerel the opportunity of demonstrating some of the remarkable properties of radium and showing by shadow-photographs the analysis of the various kinds of rays it emits. Profs. Voigt and Nernst also gave interesting communications.

In the evening the court, the teaching staff and the delegates dined together in the Whitworth Hall. This function was a private one.

The students who had assisted as spectators on Wednesday and Thursday organised a torchlight procession followed by a smoking concert on Friday evening. Since then the shadows of the terminal examination have fallen on the College.

The following extracts from the complete reports of the ceremony given in the *Manchester Guardian* are of interest:—

The Duke of Devonshire, president of the College, in the course of his opening remarks, said that the idea of the founder was to provide higher education in such branches of learning and science as are usually taught in the English universities. The original idea was thus education of the university type, such as that which had prevailed at the old Universities of Cambridge and Oxford.

The foundation of the College coincided nearly in time with great discoveries in science, and at the same time with inventions which provided the means of using those discoveries for the purpose of industry, and it is these discoveries which have stimulated interest in those studies of natural science in which Owens College has been preeminently distinguished. This is the interest to which, in the main, Owens College has been indebted for its success. Students have no doubt been attracted by the eminence of some of its teachers from all parts of the country, but, in the main, those students have been drawn from Manchester and its immediate neighbourhood. They have come here doubtless with the desire, with the hope, of acquiring knowledge, that knowledge and training which would be of practical use to them in the future occupations of life. But, at the same time, Owens College has never been content to limit the range of its teaching to one or two subjects or one set of subjects. It has never been content to be merely a medical or a legal or a technical college, but it has set before itself the aim of teaching—of a true university type of teaching—which shall embrace all branches of knowledge.

The address from the College to the Prince of Wales was then read by the principal, and in his reply His Royal Highness remarked:—

"On this first jubilee-day of your College the question may be fairly asked whether it has fulfilled the object of the founder. We are told that his idea was to provide, in a great centre of population, commerce and industry, 'higher education in such branches of learning and science as were usually taught in the English universities.' Those who joined with Mr. Owens in this scheme recognised that in the great commercial centres there was both the opportunity for and the need of something in the nature of real university life. Perhaps the best proof of the wisdom of the policy adopted in the case of Owens College is the fact that in nearly all the largest towns of the country there have been founded during the last thirty years colleges to a very large extent on similar lines. Owens College has sent many teachers, not only to these, but to the old Universities of Oxford and Cambridge. And we may also, on this jubilee-day, take stock of those influences which have been instrumental in thus successfully developing and carrying out the original scheme of the founders. Will Owens College ever cease to venerate the names of Owens, Beyer, Christie, Whitworth, and other noble benefactors to whose munificence is chiefly due her creation, endowment and material prosperity? Can she ever be sufficiently grateful to those great teachers and students who have not only by their genius and force of intellect maintained in the College a high standard of learning, but also by their personal example have helped to form the characters and guide the lives of those who have been so fortunate as to come under their influence? Amongst these former eminent leaders, two—Dr. Ward and Sir Henry Roscoe—are, I am sorry to say, prevented by illness from taking part in to-day's ceremony. But great as have been these different forces in building up this vast and important educational machinery, they would not be sufficient without the strength and sustenance which has been secured by local patriotism and local enthusiasm. I feel sure that Owens College may always count with confidence upon a generous local municipal support to enable it to keep abreast of the ever-growing demands of modern life, whether it be in the arts, in science, or other departments of a liberal education."

In connection with the celebration, the honorary degree of D.Sc. was conferred by the Victoria University upon the following distinguished men of science:—Presented by Prof. Young, Dean of the Medical Department: Sir Thomas Barlow, Sir J. S. Burdon Sanderson, Sir W. S. Church, Mr. H. G. Howes and Prof. Simpson. Presented by Prof. Schuster: Prof. Becquerel (Paris), Prof. Chodat (Geneva), Prof. G. Carey Foster, Dr. J. W. L. Glaisher, Principal E. H. Griffiths, Principal Hicks, Dr. E. W. Hobson, Prof. G. B. Howes, Prof. W. Jack, Principal Lodge, Prof. Nernst (Göttingen), Prof. Poynting, Prof. Tilden, Prof. Voigt (Göttingen), and Prof. Marshall Ward. The honorary degree of M.Sc. was conferred upon Mr. C. Bailey, Mr. Francis Jones and Mr. J. H. Reynolds.

CELEBRATION OF THE TWENTY-FIFTH ANNIVERSARY OF THE JOHNS HOPKINS UNIVERSITY.

THE twenty-fifth anniversary of the foundation of the Johns Hopkins University was celebrated at Baltimore last month. The commemorative address delivered by Dr. D.C. Gilman, for twenty-five years president of the University, and now president of the Carnegie Institution, is published in *Science*, together with the address delivered by Prof. Remsen upon his inauguration as president of the University. The assembly was one of the most noteworthy that has been gathered together in America, being composed of leaders in many branches of intellectual activity. In the course of the ceremonies an address, signed by more than one thousand alumni of the university and others, was presented to Dr. Gilman. We give extracts from the addresses delivered by Dr. Gilman and Prof. Remsen.

In the course of his address Dr. Gilman said:—

When this university began, it was a common complaint, still uttered in many places, that the ablest teachers were absorbed in routine and were forced to spend their strength in the discipline of tyros, so that they had no time for carrying forward their studies or for adding to human knowledge. Here the position was taken at the outset that the chief professors should have ample time to carry on the higher work for which they had shown themselves qualified, and also that younger men, as they have evidence of uncommon qualities, should likewise be encouraged to devote themselves to study. Even those who were candidates for degrees were taught what was meant by profitable investigation. They were shown how to discover the limits of the known; how to extend, even by minute accretions, the realm of knowledge; how to cooperate with other men in the prosecution of inquiry; and how to record in exact language, and on the printed page, the results attained. Investigation has thus been among us the duty of every leading professor, and he has been the guide and inspirer of fellows and pupils, whose work may not bear his name, but whose results are truly products of the inspiration and guidance which he has truly bestowed.

The biological laboratory, the first establishment of its kind in the United States, has carried forward for many years the study of marine life at various points on the Atlantic and has published many important memoirs, while it has trained many able investigators now at work in every part of the land. Experimental psychology was here introduced. Bacteriology early found a home among us. The contributions to chemistry have been numerous and important. Here was the cradle of saccharine, that wisely diffused and invaluable concentration of sweetness, whose manufacturers unfortunately do not acknowledge the source to which it is due. In the physical laboratory, light has been thrown upon three fundamental subjects—the mechanical equivalent of heat, the exact value of the standard ohm, and the elucidation of the nature of the solar spectrum. For many years this place was the chief seat in this country for pure and advanced mathematics.

I cannot sit down without bringing to your minds the memories of those who have been with us and have gone out from us to be seen no more: Sylvester, that profound thinker devoted to abstractions, the illustrious geometer whose seven prolific years were spent among us and who gave an impulse to mathematical researches in every part of this country; Morris, the Oxford graduate, the well-trained classicist, devout, learned, enthusiastic and helpful, most of all in the education of the young; accomplished Martin, who brought to this country new methods of physiological inquiry, led the way in the elucidation of many problems of profound importance, and trained up those who have carried his methods to every part of the land; Adams, suggestive, industrious, inspiring, versatile, beneficent, who promoted, as none had done before, systematic studies of the civil, ecclesiastical and educational resources of this country; and Rowland, cut down like Adams in his prime, honoured in every land, peer of the greatest physicists of our day, never to be forgotten in the history of physical science. I remind you also of the early student of mathematics, Thomas Craig, and of George Huntington Williams, the geologist, whose memory is cherished with admiration and love. Nor do I forget those who have here been trained to become leaders in their various departments throughout the country. One must be named, who has gone from their number, Keeler, the gifted astronomer, who died as the chief of the Lick Observatory in California, whose contributions to astronomical science place him among the foremost investigators of our day; and another, the martyr Lazear, who, in order that the pestilence of yellow fever might be subdued, gave up his life for humanity.

Prof. Remsen chiefly dealt in his address with the development of the university idea in America, and showed that the noteworthy characteristic of educational work in recent years is the philosophical faculty in the universities and the surprisingly rapid increase in the attendance upon the courses in such faculties. He remarked:—

In 1850 there were 8 graduate students in all the colleges of America. Of these, 3 were enrolled at Harvard, 3 at Yale, 1 at the University of Virginia and 1 at Trinity College. In 1875 the number had increased to 399. In 1900 the number was 5668. At present the number cannot be far from 6000.

In order that these facts may be properly interpreted, we should know how many Americans are studying in foreign

universities. The records show that in 1835 there were 4 American students in the philosophical faculties of German universities; in 1860 there were 77; in 1880, 173; in 1891, 446; in 1892, 383; in 1895, 422; and in 1898, 397.

These figures show clearly that the increase in the attendance at American universities is not accounted for by a falling off in attendance at German universities. On the other hand, they do show that for the last ten years at least there has been no increase in the attendance at German universities, but rather a slight decrease.

Six thousand students are, then, to-day pursuing advanced courses in American universities, while not longer ago than 1875 the number was only about 400. In this connection it must further be borne in mind that during this period the colleges have not relaxed in their requirements. The tendency has been in the opposite direction. So that it means to-day more rather than less than it did in 1875 to be a graduate student. That there is an increasing demand for university work is clear, and it seems to be destined to play a more and more important part in the development of educational methods.

University work is not something apart, independent of other kinds of educational work. It is a necessary part of the whole system. It affects not only the colleges, but schools of all grades, and must, therefore, have a profound influence upon the intellectual condition of the whole country.

But the universities are also doing another kind of work of importance to the country. Through their specially prepared men they are doing something to enlarge the bounds of knowledge. To be sure, such work is also being done to some extent in colleges and elsewhere, but the true home of the investigator is the university. This work of investigation is as important as the work of training men. What does it mean? All persons with healthy minds appear to agree that the world is advancing and improving. We see evidences of this on every side. Those results that appeal most strongly to mankind are, perhaps, the practical discoveries that contribute so much to the health and comfort of mankind. These are so familiar that they need not be recounted here. If great advances are being made in the field of electricity, in the field of medicine, in the field of applied chemistry, it is well to remember that the work that lies at the foundation of these advances has been done almost exclusively in the universities. It would be interesting to trace the history of some of these advances. We should find that in nearly every case the beginning can be found in some university workshop where an enthusiastic professor has spent his time prying into the secrets of nature. Rarely does the discoverer reap the tangible reward of his work—that is to say, he does not get rich—but what of it? He has his reward, and it is at least a fair question whether his reward is not higher than any that could be computed in dollars and cents.

The material value to the world of the work carried on in the university laboratories cannot be over-estimated. New industries are constantly springing up on the basis of such work. A direct connection has been shown to exist between the industrial condition of a country and the attitude of the country towards university work. It is generally accepted that the principal reason why Germany occupies such a high position in certain branches of industry, especially those founded upon chemistry, is that the universities of Germany have fostered the work of investigation more than those of any other country. That great thinker and investigator, Liebig, succeeded during the last century in impressing upon the minds of his countrymen the importance of encouraging investigations in the universities, and since that time the German laboratories of chemistry have been the leaders of the world. In Germany the chemical industries have grown to immense, almost inconceivable, proportions. Meanwhile the corresponding industries of Great Britain have steadily declined.

What I want to make clear is that universities are not luxuries, to be enjoyed or not, as we may please. They are necessities. Their work lies at the very foundation of national well-being.

The best thing we can do for our students is to give them good professors. Sumptuous laboratories, large collections of books and apparatus, extensive museums are well enough. They are necessary, no doubt. But I fear they are too much emphasised before the public. A university is, or ought to be, a body of well-trained, intelligent, industrious, productive teachers of high character provided with the means of doing their best work for their students, and therefore for the world.

NOTES.

PROF. WINOGRADSKY, of St. Petersburg, has been elected a correspondant of the Paris Academy of Sciences, in the Section of Rural Economy.

THE seventy-fourth meeting of the German Association of Naturalists and Physicians is this year to be held on Austrian soil, Carlsbad being the town selected, and the date September 21 to 27. The arrangements will be generally the same as those introduced at Hamburg last year, but it has been decided to add a new division to the medical group—the history of medicine—so that the scientific side will be represented by eleven divisions, as before, and the medical by seventeen.

THE following are among the lecture arrangements at the Royal Institution, after Easter:—Dr. Allan Macfadyen, three lectures on recent methods and results in biological inquiry; Prof. Karl Pearson, three lectures on the laws of heredity, with special reference to man; Prof. Dewar, three lectures on the oxygen group of elements; and Dr. A. Smith Woodward, three lectures on recent geological discoveries. The Friday evening meetings will commence on April 11, when Prof. Dewar will deliver a discourse on problems of the atmosphere. Succeeding Friday evening discourses will be delivered by Dr. J. Mackenzie Davidson, Sir Robert Ball, Sir Benjamin Baker, Mr. A. E. Tutton, and other gentlemen.

WE regret to see the announcement of the death of Sir Richard Temple, Bart., M.P., F.R.S., whose personality was well known in scientific and educational circles. He was vice-chairman of the School Board of London for three years from 1885 and afterwards chairman of the finance committee of the Board. He was also president of the Social Science Congress held at Huddersfield, and the author of several works on Indian and Eastern topics.

THE death is announced of Mr. Robert Pendlebury, fellow of St. John's College, Cambridge, and well known by his mathematical work. Mr. Pendlebury graduated in the mathematical tripos of 1870 as senior wrangler. He also graduated at the University of London, obtaining the senior University scholarship for mathematics and natural philosophy. He was in due course elected to a fellowship at St. John's, and for many years was one of the college lecturers in mathematics. He was also University lecturer in mathematics, but recently resigned all his appointments. He had been an examiner for the mathematical tripos on several occasions, and for some time a member of the Special Board for Mathematics.

WE learn from the *Victorian Naturalist* that the Central Australian expedition under the leadership of Prof. Baldwin Spencer and Mr. F. J. Gillen reached the Macarthur River, Northern Territory, but was detained at Borroloola, a small township about 50 miles from the mouth of the river, owing to the foundering of the steamer which should have taken them on to Port Darwin as previously arranged. The matter of affording the expedition some relief was brought before the Commonwealth Parliament without result. However, the Premier of Victoria (Hon. A. J. Peacock) placed himself in communication with the Queensland Government, and it was arranged to send a small steamer from Normanton and bring the party on to that port, from whence there is frequent communication with eastern Australia.

IT is announced in the *Times* that the two Royal medals of the Royal Geographical Society have been awarded to Sir F. D. Lugard, for his African explorations and surveys, and to Major Molesworth Sykes, for his journeys in Persia, extending over nine years, and his valuable studies of the geography of the country. The other awards of the society have been made

as follows:—The Murchison grant to Mr. J. Stanley Gardiner, for his researches in Funafuti Island in the Pacific and the Maldive Islands in the Indian Ocean; the Gill memorial to Mr. G. G. Chisholm, for the services he has rendered during twenty-five years to geographical education by text-books of various kinds, atlases and lectures, all of a high standard of value, as well as for his geographical investigations, among other subjects into cataracts and waterfalls, and on the sites of towns; the Back grant to Lieut. Amdrup, of the Danish navy, for his two voyages of exploration to the east coast of Greenland, during which he surveyed and mapped in detail much of the coast hitherto unknown or imperfectly mapped; the Peek award to Mr. J. P. Thomson, the founder of the Queensland branch of the Australian Geographical Society, who, by his writings and in other ways, has done much to promote the interests of geography in Queensland.

THE Naples Academy (mathematical and physical section) has awarded the prize for natural sciences for 1901 to Dr. Marussia Bakunin, the authoress of six printed papers dealing with stereochemistry. The subject announced for the next award (entries closing June 30, 1903) is the formation of urea in the animal organism.

THE prize awards of the Reale Istituto Lombardo for the year 1901 are as follows:—Triennial medals to Prof. Giuseppe Sartori, of Brescia, for preparation of butter with acidified cream, and to Pietro Gamberini, of Milan, for photographic apparatus. Under the Brambilla foundation, a gold medal and 1000 lire to the Società del Laminatojo di Malavedo for the production of soft steel, a similar award to Franchi e Griffin for the wheels of tempered iron (suitable for tramcars and other rolling stock) made by the Griffin process, and a gold medal and 500 lire to Turrinelli and Company for their introduction into Milan of a service of public automobiles worked by electricity. A Fossati foundation award of 1000 lire to Dr. Carlo Martinotti, of Turin, for his macro- and micro-scopic researches on the encephalus of the higher animals. Pizzamiglio foundation prizes of 1500 lire to Dr. Alfredo Piazzi, of the University of Turin, and of 750 lire to Dr. Guido Jona, of Savona, for essays on secondary education. Under the Tommasoni foundation, for studies of the life and works of Leonardo da Vinci, awards of 1000 lire to each of the three competitors, comprising Dr. N. S. Scognamiglio, Prof. G. B. de Toni and Edmondo Solmi.

THE number of the *Rendiconti* of the Lombardy Institution containing the announcements of prize awards also gives a list of future subjects for prizes. Of the prizes of the Institution, that for the present year (entries closing March 31, 3 p.m.) is for a toponomastic exploration of some district of Lombardy; that for 1903 is for some original contribution to our knowledge of the theory of transformation-groups as founded more particularly by Liè. The two triennial medals for 1903 will be offered, as usual, for improvements in the agriculture and in the manufacturing industries in Lombardy. For the Cagnola prizes, the subjects selected by the Institution are, for 1902 (entries closing April 1), the study of the effects of the gases emanating from various manufactories on the growth of cultivated plants, and for 1903, a monographic study of hypophysis. The four subjects selected by the founder for the remaining Cagnola prizes deal with the the cure of pellagra, the nature of miasma and contagion, aërial navigation, and the prevention of forgery, and in connection with the second subject it is suggested in a footnote that competitors might deal with prophylactic measures against malaria considered in connection with our present knowledge of the biology and mode of diffusion of the microbe of this disease. The Brambilla prize is offered for improvements in the manufactories of Lombardy. The Fossati prize for 1902 is for macro- and micro-scopic researches on the encephalus of the higher animals, for 1903 on the nuclei of origin or termination of the cranial nerves, and for 1904 on the localisation of certain cerebral centres. The Kramer prize, confined to Italian engineers, is offered for a report on systems of electric traction. The Secco-Comneno prize is for a description of the Italian natural phosphatic deposits and their practical uses (entries closing April 30, 3 p.m.). A prize is offered under the Pizzamiglio foundation to Italians for an unpublished manuscript on the influence of modern socialistic doctrines on private rights. Ciani prizes are offered for popular Italian literary works, a triennial Zanetti prize (entries closing March 31) is offered to an Italian pharmaceutical chemist who shall obtain a result which is considered of use in the progress of pharmaceutical and medical chemistry, and a Tommasoni prize for 1905 for a study of the life and works of Leonardo da Vinci.

THE thirteenth session of the International Congress of Americanists will be held in the American Museum of Natural History, New York City, October 20-25. The object of the Congress is to bring together students of the archæology, ethnology and early history of the two Americas, and by the reading of papers and by discussions to advance knowledge of these subjects. Communications may be oral or written, and in French, German, Spanish, Italian or English. The papers presented to the Congress will, on the approval of the Bureau, be printed in the volume of the *Proceedings*. The subjects to be discussed by the Congress relate to:—(1) The native races of America, their origin, distribution, history, physical characteristics, language, inventions, customs and religions; (2) the history of the early contact between America and the Old World. All persons interested in the study of the archæology, ethnology and early history of the two Americas may become members of the Congress by signifying their desire to Mr. Marshall Saville, general secretary of the Commission of Organisation, American Museum of Natural History, New York, and remitting either direct to the treasurer (Mr. Harlan I. Smith, American Museum of Natural History) or through the general secretary, the subscription of three dollars. Mr. Morris K. Jesup is president and the Duke of Loubat vice-president of the Commission of Organisation.

THE Government Report of the Committee on Acetylene Generators, which has just been issued by H.M. Chief Inspector of Explosives, shows that the acetylene industry has attained a position of no little importance. Consisting of some thirty pages, the Report, which is the outcome of the work of a strong committee, contains some valuable tabulated results of tests on forty-six specified generators, showing their gas production, efficiency, and maximum pressure in the generating chamber and in other parts of the plant. It speaks very highly for the industry that every one of these generators sent in for examination has been reported by the Committee to be satisfactory. We share the opinion of the Committee that many of the generators on the market are too complex in construction, and when prime cost, space, loss of water and of gas by solution are not important considerations, we agree with the view that the non-automatic generator, on account of its certainty and simplicity, is to be preferred to the automatic type. A list of what the Committee consider the conditions which a generator should fulfil in order to be considered safe should be of great value to those engaged in the design of acetylene plant. The only thing to which exception may be taken is a limit of five inches water pressure suggested for the gas in the service mains; by raising this limit to six or seven inches, the possibilities of using the gas for heating purposes would be greatly increased, and, as we believe that it is generally admitted that under pressures of less than two atmospheres there is no danger of spontaneous decomposition, such an increase does not seem

objectionable, though a three to four inch limit might be imposed for lighting purposes alone. We should like to have seen some remarks upon the purification of the gas and the ventilation of buildings in which it is used in an unpurified condition. Two-thirds of the Report is devoted to the description, with many illustrations, of the types of generators tested. This is valuable as a summary of the catalogues of various makers, but we wish the Committee had seen its way to make some criticisms upon these various types, as was done some time ago by those responsible for the exhibition of generators which was held at the Imperial Institute.

AN advance proof of a Parliamentary paper, received from the Home Office, shows that the total output of coal of the United Kingdom in the year 1901 amounted to 219,037,240 tons, as compared with 225,170,163 tons in the preceding year. The outputs of some other minerals were as follows, the numbers representing tons:—copper ore and copper precipitate, 6792; iron ore, 1,671,025; ironstone (worked under Coal Mines Regulation Acts), 6,849,926; lead ore, 32,552; rock salt, 151,348; tin ore (dressed), 6542; zinc ore, 23,582.

PROF. HERDMAN has written to Mr. I. C. Thompson to say that his investigation of the pearl fisheries of the Gulf of Manaar is being greatly facilitated by everyone interested in it at Ceylon. A steamer—the *Lady Havelock*, of three hundred tons—has been chartered, and a start was made at the end of January. Dr. A. J. Chalmers has given Prof. Herdman the use of a room in his laboratory at Colombo, and Mr. J. C. Willis has offered a work place in his laboratory at the magnificent Botanic Gardens at Peradeniya. Prof. Herdman adds:—"I found up country at Anurhadapura (one of the 'buried cities' of Ceylon) the two Germans, Dr. Paul and Dr. Fritz Sarasin, who have been exploring for years in Ceylon, and were the only people who could give me information about Trincomalee, where I wish to dredge. Finally, I met Prof. Alex. Agassiz, just returned from his expedition to the Maldive archipelago, and he kindly lent me 600 fathoms of especially strong and flexible steel rope, which will be a valuable addition to our tackle. Prof. Agassiz, you will be interested to hear, says he has had a most successful trip, and has secured all the information, photographs and specimens of the coral reefs that he desired. He says the Maldives are the last of the great coral archipelagoes which he had set before himself to examine, and that now he is prepared to write his book on the general subject, 'Coral Reefs and Islands.' There can be no doubt that he has a much more extended personal knowledge of the reefs of the world than Darwin, Murray, or any other previous writer."

AN interesting description of an experimental locomotive appears in the *Times* of March 12. The boiler is an entire departure from ordinary practice; in fact, it may be called a water-tube boiler applied to the locomotive. To Mr. Dugald Drummond, of the London and South-Western Railway, is due the credit for this innovation, and it will be interesting to watch its development. Mr. Drummond has long experimented with water-tubes in the fire-box of the ordinary locomotive with much success, a system originally patented by Mr. W. S. Smith, of the North-Eastern Railway. The modified boiler consists of an ordinary locomotive boiler shell and an ordinary shaped fire-box, but in place of the large number of tubes usually used, one large flue-tube is fitted and this contains many water-tubes; there are also water-tubes in the fire-box. It will, therefore, be seen that the products of combustion on their way from the fire-box to the smoke-box must pass through the large flue-tube and encounter the many water-tubes in it. The locomotive fitted with this boiler has been working the west country expresses between Waterloo and Salisbury with gratifying results. Steam is stated to be maintained with ease. The coal consumption recorded with a train of twelve carriages was under 29 lbs. per mile; it would have been more satisfactory, however, had the weight of the train been stated, because the consumption is decidedly low. This type of boiler should be of much use on locomotives of the ten-wheeled description. The excessive length of ordinary tubes required in this class is out of all proportion, from a heating-surface point of view, such engines having tubes nearly 16 feet long and only 2 inches in diameter, whereas with Mr. Drummond's new boiler a long barrel would be a decided advantage. It is evident that very perfect combustion is possible; the gases are well mixed in the large flue and the flame is less likely to be extinguished on its way to the smoke-box.

A PAPER by Mr. T. R. Rao on the Yánádis of the Nellore district, Madras Presidency, appears in the *Bulletin* (vol. iv. No. 2) of the Madras Government Museum, from which the accompanying illustration of a method of making fire has been reproduced. To produce fire by friction in this way, the Adivi or forest Yánádis prepare two sticks—one short, the other long. In the former a square cavity is made, and it is held firmly on the ground, while the long stick is twirled rapidly to and fro in the hole. No charcoal powder is used, but a rag, or even dried leaves, are ignited. The Yánádis possess the characteristics of jungle tribes, and are little removed from savagery, the culture being that of the Palæolithic stage. This is indicated by the absence of implemental or monumental material, the animistic, and to some extent zoo-theistic, nature of the religion, the primitive hunting and fishing methods followed by many of the tribe, and the habit of eating the almost raw flesh of the game they kill, after slightly heating or scorching it. The Yánádis are fearless in catching cobras, which they draw out of their holes without any fear of their fangs. They appear to protect themselves against the effects of snake-bite by swallowing the poison sacs of snakes.

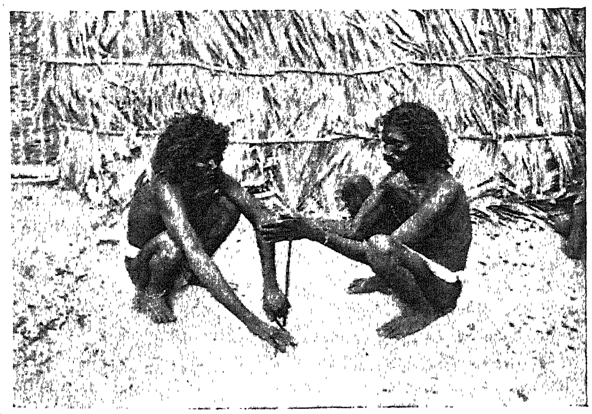

FIG. 1.—Yánádis making Fire.

IN a paper entitled "Environment in Relation to Sex in Human Culture" in the *Popular Science Monthly* for January, Dr. Otis T. Mason gives a series of notes on the main characteristics of the chief cultural areas of America which will be useful to those who desire to obtain a general survey of aboriginal American sociology.

IN the *American Anthropologist* (n.s. vol. iii. p. 737), Dr. G. A. Dorsey describes the recent progress in anthropology at the Field Columbian Museum in Chicago. Thanks to an energetic and efficient staff and the enlightened liberality of Chicago merchants, this museum is fast assuming a place in the

front rank of the great anthropological museums of the world. This record by Dr. Dorsey is enough to make us feel ashamed of ourselves in this country, as it is only a sample of what is being done in other American museums and institutions.

THE most interesting article to the general reader in the current number of the *Bulletins et Mémoires de la Société d'Anthropologie* (v. sér. tome 2) is one by M. C. Lejeune on the representation of sex in religion, art and education. A paper on the normal and varietal myology of the fox appears out of place in an anthropological journal. Various reproductions are given by M. E. Rivière of the mural paintings of animals from the cave of La Mouthe, similar to those to which we have recently directed attention (p. 299). It will be remembered that M. Rivière was the first to discover these paintings. A paper by M. G. Cauderlier on the causes of the depopulation of France gave rise to an interesting discussion.

IN the *Bulletin* issued by the Botanical Department at Trinidad and edited by Mr. Hart, under the heading of "Root Irritation," reference is made to the difficulty of planting out young mangosteens, cloves, or Palmyra palms. If the seeds have been started in pots, when transferred to the open ground the young plants have a strong tendency to die off. It is suggested that this may be due to the tender nature of the roots or root hairs, which seem to suffer if they are disarranged or carelessly handled in the process of transplanting. In the case of the mangosteen this question has a most important bearing, for the life of the seed is so fugitive that it becomes necessary to start the seed in pots if plants are to be forwarded to a distance; then besides the necessity for keeping the plant in good growing condition on the journey, there is the added danger of losing it when it is transplanted. Another extract from the same paper refers to the slow and irregular germination of balata seeds (*Mimusops globosa*), which may take any period from three months to two years. These seeds have a hard exterior which takes up water slowly, so that germination would probably be accelerated by piercing the seeds before sowing.

A SMALL pamphlet issued by the Indiana Agricultural Experiment Station deals with two plant pests, the horse nettle and the buffalo bur, both specimens of Solanum. The former, *Solanum Caroliniense*, has travelled north from the county after which it has been named. Propagation is effected by underground shoots and also by seed. While it is easy to prevent the plant seeding, shoot propagation is not so easily checked. Ploughing cuts up the shoots, and then each portion may develop independently. Constant hoeing, however, provides a remedy, as by continual cutting the propagative power is finally exhausted; or the plant may be smothered by sowing rape or barley or other quick-growing crops. The buffalo bur, *Solanum rostratum*, has a spiny stem and fruit. It is a typical xerophyte from the south-west, from the counties of Texas and Nebraska. It seems to have been carried eastward as an impurity with other seeds. Being an annual it is more easily strangled, although it has an illicit habit of throwing up short fruiting branches if it is cut near the surface of the ground.

AMONG several interesting biological articles in the *Sitzungsberichte* of the Bohemian Scientific Society for 1901, one by Dr. J. V. Rohon on the anatomy and histology of the Devonian dermal plates and spines described as Psammosteus is of special importance. It was pointed out by Agassiz and Pander that the histological structure of these spines seemed to indicate affinity with the sharks; and Reis concluded that both Psammosteus and Pteraspis were degenerate selachians. This view is not accepted by the author, who regards both these groups of armour-clad Devonian fishes as specialised types, indicating two nearly related families. In Dr. Smith Woodward's "Catalogue of Fossil Fishes in the British Museum" the systematic position of Psammosteus was left undetermined, although some countenance was given to the theory of its selachian affinity. To the same serial Mr. J. Palacký contributes an article on the distribution of edentates and another on that of bats.

IN the *Aarbog* of the Bergen Museum for 1901, Mr. O. Nordgaard gives the results of his investigations as to the food of the coal-fish (*Gadus virens*) at different portions of its existence. From the stomachs of young individuals the author took no less than thirty distinct kinds of organisms. From this it appears that during the first year of its existence this cod subsists chiefly upon plankton. Generally this fare is sufficient, but if it fail the fish resorts to sea-weeds, where it feeds upon various minute crustaceans, young molluscs and even hydroid polyps. From the stomach of one individual were taken no less than 6250 copepod crustaceans—representing the average fauna of about 20 cubic yards of water. The stomachs of older coal-fish contained herrings, sprats, the salmonoid Mallotus, sand-eels, the cephalopod Ommatostrephes, and various crustaceans, among them Boreophausia. It is further proved that coal-fish prey on their own offspring as well as on those of the cod. In the northern fjords of Norway, where very large catches of coal-fish are sometimes made (34,000 head in the autumn of 1898), the great shoals appear to be brought together by their pursuit of herrings and Ommatostrephes. In December and January, however, a great influx of spawning coal-fish reaches the western coast of Norway.

WE have received a copy of the extremely interesting and suggestive presidential address on "The Nature of Disease," delivered by Sir T. N. Fitzgerald before Section H of the Australasian Association at Hobart in January last. After referring to the importance of sanitation, the president of the section dwelt on the evidence in favour of the hereditary nature of neurotic affections, and—in contrast to this—the comparative rarity with which deformities and malformations are inherited. In this connection he deprecated the common prejudice against the marriage of cousins, which he regarded in many respects as specially suitable. Physical diseases, other than syphilis, are also regarded as non-hereditary; and the theory of the transmissibility of many of them by infection is strongly supported. Consequently, the author of the address is greatly in favour of the isolation and notification of phthisis. In treating of the intrinsic causes of disease, emphasis was laid on the part played by bacilli, and some interesting observations are added in reference to the readiness with which the bacillary hypothesis was received by the medical profession almost as soon as it was propounded. In reference to the harm caused by alcoholism, the following sentences are worthy of quotation:—"The bicycle, I venture to say, has done more to elevate the people in the matter of temperance than a week of lectures have been able to effect. It is in this direction, then, in my opinion, that philanthropists should work. I have lived too long not to recognise 'the dullness of the lives of the masses,' and how productive of evil this lack of variety must be."

THE fifth volume of the new edition of Thompson's "Gardener's Assistant," edited by Mr. William Watson, has been published by the Gresham Publishing Company. When the sixth (and last) volume has appeared, the complete work will be reviewed.

THERE is only one opinion among men of science as to the necessity for spreading abroad the gospel of scientific truth and righteousness taught by Huxley. A sixpenny edition of a selection of his "Lectures and Essays," just published by Messrs. Macmillan and Co. in conjunction with the Rationalistic Press Association, should do much to cultivate this

desirable interest in science and philosophy. The contents include lectures on evolution and the physical basis of life, and essays on aspects of agnosticism and ecclesiasticism which may lead incipient rationalists to firm ideas "on the nature, the duties and the non-insoluble problems of human life."

A COPY of Hazell's Annual for 1902, edited by Mr. W. Palmer, was received a few days ago from the publishers, Messrs. Hazell, Watson and Viney, Ltd. The annual is so well known and widely used that little need be said as to the character of the contents. Certainly no better epitome of the subjects which attracted general attention during last year is available; and no manual can be better depended upon to give concise and accurate information concerning public men and affairs and national interests. Among the subjects of new articles in the present edition we notice anthropology, archæology, astronomy, biology, chemistry, electricity, geography, geology, meteorological office, motor vehicles, photography, telephones and universal time. Under each of these headings a short account is given of progress made during last year. These summaries are naturally of very little value to the student of science, but they serve to give general readers a view of some of the results attained. Under biology, less than a dozen subjects are mentioned—all of them zoological—and there is no reference to botany either under this heading or elsewhere in the book. Other subjects we miss are physics, metallography (to which a paragraph might well have been devoted), radiations from radium and similar substances, malaria and mosquitoes. In the list of educational associations we find the usual secondary school organisations, but not the Association of Technical Institutions, to which practically all the principals of our technical school belong.

THE overproduction of alcohol, a consequence of the overproduction of sugar, has led to many attempts to increase its use for purposes of lighting and heating. In contrast to the repressive action of our own authorities in this matter, the strangling action of which in our chemical industries is well known, M. Jean Dupuy, the French Minister of Agriculture, organised a conference in December last to discuss the best means of extending the use of denatured alcohol for lighting and heating. The current number of the *Bulletin de la Société d'Encouragement pour l'Industrie Nationale* contains a report of this conference by M. Lindet, and gives a complete account of the numerous forms of alcohol burners which have been devised both for lighting and heating. In conclusion, M. Lindet discusses the question as to the cost of heating and lighting by alcohol in comparison with the methods in current use, and especially with reference to petroleum, and points out that although petroleum has a slight advantage in the matter of cost, this is more than counterbalanced for domestic purposes by the cleanliness and freedom from smell of the alcohol.

THE same number of the *Bulletin* contains an interesting review, by M. Ach. Livache, of the methods in use for the destruction or utilisation of town refuse. The processes in use fall mostly under two types, incineration, which has been chiefly developed in this country, and treatment by reduction, in which either a solvent or superheated steam is used. The latter is mostly in favour in the United States. The relative advantages of the two methods are critically examined, it being pointed out that no hard and fast rule can be laid down which will be applicable to all cases, a careful examination and analysis of the refuse which it is proposed to treat being an indispensable preliminary.

THE additions to the Zoological Society's Gardens during the past week include a Green Monkey (*Cercopithecus callitrichus*) from West Africa, presented by Mrs. A. Clayton; a Common Otter (*Lutra vulgaris*) British, presented by Mr. W. H. Radcliffe Saunders; a Naked-footed Owlet (*Athene noctua*) European, presented by Mrs. Tewson; a Larger Hill Mynah (*Gracula intermedia*) from Northern India, presented by Miss F. V. Cooper; a Mute Swan (*Cygnus olor*) European, presented by Mr. R. S. Lindley; a South African Ground Hornbill (*Bucorvus cafer*) from Zululand, presented by Major C. H. Rowley, D.S.O.; three Lions (*Felis leo*) from South-west Africa; a Malayan Bear (*Ursus malayanus*) from Malacca; a Bennett's Cassowary (*Casuarius bennetti*) from New Britain, deposited; two Common Rheas (*Rhea americana*) from South America; a Sœmmerring's Pheasant (*Phasianus soemmerringi*) from Japan; twelve Goldeneyes (*Clangula glaucion*) European, purchased.

OUR ASTRONOMICAL COLUMN.

NEBULA AROUND NOVA PERSEI.—A circular from the Centralstelle at Kiel announces the receipt of an interesting communication from Prof. Max Wolf concerning the changes in the nebulous surroundings of Nova Persei. On March 5 he obtained a fine photograph with an exposure of four hours, which showed that all the former condensations had become weaker. From the Nova towards the south-west there now extends a new long zone of nebulosity much brighter than the previously existing condensations. Indeed on February 3, the date of the last previous photograph, this region was very bright. It is extremely interesting that this later nebulosity is brighter than the appearance of August, 1901. The same circular also announces a communication from the Lick Observatory stating that from recent photographs with the Crossley reflector Perrine finds no evidence of polarisation in condensations A and D of the Nova Persei nebula.

NEW VARIABLE STAR, 3, 1902 (MONOCEROTIS).—Prof. W. Ceraski, of Moscow, announces the variability of the star B.D. + 6°·1462,

$$\left.\begin{array}{l}\text{R.A.} = 6\text{h. } 50\text{m. } 37\text{s.}\cdot 4\\ \text{Decl.} = +6^\circ\ 21'\cdot 4\end{array}\right\}(1855\cdot 0).$$

The star was near maximum about February 20, being then about 7·0 mag. The determination was photographic, but there is not sufficient data yet available to calculate the period. The magnitude in the B.D. is 8·0 (*Astronomische Nachrichten*, Bd. 158, No. 3775).

SEISMOLOGY IN AUSTRIA.

AT the present time the shelves of libraries throughout the world are bending beneath volumes of statistics, the analysis of which it is hoped will lead to the discovery of something new. To these piles of undigested materials, if we surmise correctly, there is shortly to be added an inundation of statistics from those who study earthquakes. Twenty years ago, seismologists were few and far between, but now they have increased in number and are represented by organised societies, which publish journals and reports. The first of these had its origin in Japan. Fifteen years later a corresponding body appeared in Italy, following on the heels of which came commissions and committees with similar objects in various European countries. Even the time-honoured routine of many meteorological and magnetical observatories has not been allowed to rest in peace, and the daily round at these establishments includes a visit to the seismographs.

As illustrative of these new departures, we call attention to what is being done by the Royal Academy of Sciences in Vienna. In 1895 this body established a Commission for the Observation of Earthquakes, the reports of which were published in the Academy's *Transactions*. Possibly on account of their size they are now issued as separate numbers, twenty-one of which form the first series. Of the second series six parts have been issued, a brief notice of which will give an idea of the extensive and valuable investigations now being carried out in Austria.

The key to this work is found in part ii. of the series, which its author, Dr. E. v. Mojsisovics, describes as a general report of shocks recorded in Austria in the year 1900. From this

we learn that the number of earthquakes was 169 as against 190 noted in 1899 and 209 noted in 1898. To obtain these records the empire has been divided into sixteen districts, each district having its referee. Dalmatia, for example, has 423 observers, who send their observations—unfortunately for the editor—in at least three different languages, to Prof. A. Belar in Laibach.

There are five horizontal pendulum stations, four of which receive from the Government a yearly subvention of 1000 to 1100 K. A sixth station is to be installed at Pribram, one instrument to be on the surface and another at a depth of 1100 m. in the Adalbert-Schacht.

In part i. Dr. W. Láska gives a catalogue of records obtained between June 1899 and December 1900 from a three-component seismograph installed at Lemberg. From the introduction to this work it is clear that Dr. Láska has met with troubles, some of which might certainly have been avoided had he been acquainted with the experiences of his predecessors. On the second page we learn that the clock employed to drive the record-receiving photographic film has also been employed to give time marks on the same. To expect a time-piece to unroll a heavy band of paper or to turn a drum and at the same time to keep a chronometer-like rate is a false economy in which those who construct seismographs for the first time frequently indulge. Whatever inaccuracies may, in consequence of this apparent simplicity of arrangement, have crept into Dr. Láska's time determinations it was evidently his intention that what could be measured should be measured with unimpeachable exactitude. The writer has in his possession a globe which, as it could not be made in England, was purchased from abroad. Its scale is stated to be 1/25,823,716·814. Although Dr. Láska does not aim at such exactitude, he tells us that the mirror of his N.W. pendulum is 3·757 m. distant from the recording drum, whilst the period of the pendulum when hung vertically is $0^{s}\cdot31515$, to which, however, he adds that there is no certainty about the accuracy of the fourth decimal. Tables which inform us that 0·1 minute = 6 seconds, 0·2 minute = 12 seconds, &c., also convey an idea of unnecessary redundancy.

In the working of the instrument, which is installed in a cellar, a well-known bogie has been encountered. There is hardly a seismologist who has not met it, and volumes sufficiently numerous to form a moderate library have been published describing its behaviour. It is a something which causes pendulums to move fitfully, and many observers cling to the belief that it is an actual motion of the ground and either trace the same to the beating of waves on a distant shore or to some other cause. The photograms showing these movements which Dr. Láska reproduces are strikingly like those obtained from observatories all over the world. Forasmuch as a copious ventilation or the burning of a gas jet in the room thus haunted frequently results in expelling the intruders, my own opinion is that the majority of them have their origin in the movements of the atmosphere in the room rather than the movement of the ground.

To show that there may be a relationship between seismic disturbances and the movements of magnetic needles which is not mechanical, our attention is once more drawn to the ancient story of the magnet at Parc St. Maur which at the time of an earthquake was caused to move whilst a similarly formed and similarly suspended copper bar remained at rest. Our attention, however, is not drawn to the possibility that these two systems had very different natural periods of vibration.

In a supplement, suggestions are made respecting the determination of the distance of an earthquake origin from a given station from the interval which elapses at that station between the arrival of the preliminary tremors and the large waves. In recent reports issued by the British Association, especially that for 1900, it will be seen that not only have these suggestions already assumed a practical form, but also that other subjects referred to by Dr. Láska have received greater or less consideration.

Part iii. is a detailed account of earthquakes noted in German Bohemia by Dr. V. Uhlig.

In part iv. Prof. P. Franz Schwab gives the records obtained from an "Ehlert" pendulum installed at Kremsmünster. From an analysis of the records it appears that the frequency of earthquakes was much less between Apogee and Perigee than between Perigee and Apogee. In the cooler months, especially from the middle of September to the beginning of March, the pendulums were frequently unsteady. The greatest disturbances, however, accompanied marked barometric depressions. These movements probably eclipsed movements due to earthquakes.

The next number, by Dr. E. Mazelle, is a register of 146 records obtained from a Reubeur-Ehlert pendulum at Trieste.

One excellent suggestion made by Dr. Mazelle is that seismologists should have a uniform system in chronicling their observations.

The periods of his pendulums are taken monthly and are recorded to within 1/100 of a second of time, whilst a table is given to compute possible tiltings of the pendulum to within 1/1000 of a second of arc.

At the end of this paper we find certain analyses of the registers, relating, for example, to the monthly frequency and the frequency of disturbances of different amplitudes, those with amplitudes between 1 and 2 mm. forming 35 per cent. of the total observations.

The sixth part of these publications, by J. N. Woldrich, refers to the earthquake which on January 10, 1901, shook north-east Bohemia. Here and there we find reference to unusual phenomena like the swaying of forests as if moved by a strong wind, the increase or decrease of water in springs, and the effect of the movements upon men and the lower animals. The latter, excepting the story of a man who by the shaking was caused to walk in his sleep, are of the usual type.

Most of these papers are accompanied by maps or diagrams.

J. M.

SCIENTIFIC SERIAL.

THE February number of the *Journal of Botany* contains three articles dealing with mosses. The first and most interesting paper records the finding of an Arctic species, *Tetraplodon Wormskioldii*—practically a Splachnum—on Widdy Bank Fell, by Messrs. E. C. Horrell and D. A. Jones. Its usual habitat is about 70° N., and further north.—Mr. Duncan discusses the occurrence of *Octodiceras Julianum* along with Fontinalis in the River Severn.—There is the first part of a joint paper by Messrs. D. Prain and E. Baker on Indigofera species, in which it is proposed to deal with the numerous synonyms.—Mr. C. B. Clarke writes an appreciative article on Colonel Sir Henry Collett, who combined botany with various important administrative posts in India.

IN the number for March, Messrs. S. Schönland and E. G. Baker conclude a series of articles on South African species of Cotyledon.—Two sets of "Notes" deal with the distribution of plants. The first, by C. E. Salmon, enumerates floral localities in Norfolk, thereby furnishing an appendix to Trimmer's "Norfolk Flora" and the supplement thereto.—The second article, written by William Whitwell, relates to East Sussex. He alludes to the "Notes" given by Salmon in the last December number of this journal, which were more copious and referred to the whole county. These two papers, with Arnold's well-known book, should bring the Sussex flora up to date, more especially since Mr. Salmon benefited by help from Mr. Botting Hemsley and by records due to Mr. Roper.—In the supplement, Mr. Batters once again essays a catalogue of British marine Algæ, which will be very cordially welcomed. The "revised list" was published in the *Annals of Botany*, 1890, by the same writer in conjunction with Mr. Holmes. As regards localities a change will be noticed; instead of the arbitrary sections of the coast given in the revised list, specific towns, &c., are now mentioned. Practically the whole of this part deals with the Myxophyceæ, or, as they are generally termed, the Cyanophyceæ.

SOCIETIES AND ACADEMIES.

LONDON.

Physical Society, March 14.—Mr. S. Lupton, vice-president, in the chair.—A paper on the thermal expansion of porcelain was read by Mr. A. E. Tutton. The paper gives an account of experiments made to determine the expansion of Bayeux porcelain between 0° and 120° C. The material employed was a portion of the tube used by Bedford in his experiments on the expansion of porcelain between 0° and 830° C. Another piece of the same tube has also been used by Chappuis in a series of determinations by the Fizeau method between 0° and 83° C. The author has worked with an interference dilatometer, which possesses advantages over the Abbe

form of the original Fizeau apparatus. The observing part of the instrument is separated from the expansion chamber, and the temperature of the interference tripod and the substance under investigation, which it carries, is measured by means of a thermometer bent just above the cylindrical bulb and so arranged that the latter lies on the tripod table. The chief advantages over the Fizeau apparatus are briefly, (1) the employment of a micrometric method of measuring the position and width of the interference bands; (2) the use of autocollimation; (3) the employment of C hydrogen light; (4) an arrangement of the thermal chamber which readily permits an extension of the range to 120° C. The author has also introduced an aluminium compensator, a relatively thick disc of aluminium laid on the top of the porcelain tube. This overcomes the difficulty of polishing the porcelain and affords a large field of bands instead of an annular ring showing parts of bands. The mean of three determinations with three specimens of material gives the following result for the linear expansion, $L_t = L_0[1 + 10^{-9}(2522t + 7{\cdot}43t^2)]$. The results presented by the author agree tolerably well with those of Chappuis, but the constant a is slightly smaller. The constant b is seven times larger than according to Bedford. The discrepancies between the results of Chappuis and Bedford appear to be due to a fundamental real difference, dependent on the interval of temperature for which the determinations were made. The increment per degree of the coefficient of expansion of porcelain is not a constant quantity, but one which is much larger between 0° and 100° than at higher temperatures. The supposition of Prof. Callendar, as to the anomalous expansion between 0° and 100°, appears to be well founded.—The secretary then read a paper by Mr. W. Williams on the temperature variation of the electrical resistances of pure metals and allied matters. In the first part of the paper an attempt is made to correlate the periodic variations which pure metals exhibit as regards their atomic weights, chemical valencies, melting points and electric resistances. If m is the chemical valency, V the atomic volume, θ the absolute temperature, T the absolute melting point and c, or $V^{\frac{1}{3}}\alpha T$, the constant of Pictet's law, then $\sigma \propto \frac{mV\theta}{cT}$, where σ is the specific resistance at 0° C. This relation holds for most of the metals, but fails for gold, indium, tin and aluminium, and also for metals of the iron group. The temperature resistance-coefficients of pure metals are not equal to 1/273, and an expression for the change of resistance with temperature has been deduced which holds approximately for many metals. The author also obtains simple expressions for the average increment per degree of the specific heat of metals and for the ratio between the specific resistances of the solid and liquid states of a metal at the temperature of fusion.—A paper entitled "A suspected case of electrical resonance of minute metal particles for light waves; a new type of absorption," by Prof. R. W. Wood, was read by the secretary. Experiments on which the author has been engaged have led him to believe that he has found a new type of light absorption, which it may be possible to refer to the electrical resonance of small metallic particles for waves of light. Metallic deposits on glass have been produced which are shown by the microscope to consist of particles less than the wave-length of light, and which by transmitted light exhibit colours as brilliant as those produced by aniline dyes. The author has sought to explain these colours by interference and diffraction, and has been forced to accept the hypothesis suggested in the title of the paper. The metallic deposits can be obtained by heating small fragments of the alkali metals in exhausted glass bulbs, when the vapour condenses on the cold parts of the bulbs and forms the films. It can be shown that the colours are due to the presence of metallic sodium (in the case in which sodium has been used) by allowing air to enter the bulb; oxidation takes place and the film vanishes. In some experiments the air has been allowed to enter very slowly, and the changes which the film undergoes before it vanishes have been examined. The particles which form the deposits can be classed under three heads: (1) coarse particles which diffract or scatter light and give the bulb a silky lustre; (2) minute particles very close together which regularly reflect those wave-lengths absent in the transmitted light, but give no scattered light; and (3) minute particles far apart which diffuse light of the same wave-lengths as those which are to some extent absent from the transmitted light. By observing the spectrum of the transmitted light, the author has examined the changes in colour which accompany changes in temperature of the films. The paper gives an account of the relation between the colour of the film and the size and distribution of the particles, and also of the behaviour of the films with polarised light. Experiments upon the electric resistance of the films have proved that they are non-conducting. The author concludes by stating that at the present stage it is impossible to decide either in favour of, or against, the theory of resonance. The idea of resonance has proved a useful working hypothesis for explaining some of the phenomena described in the paper. The secretary read a letter from Prof. R. Threlfall directing the attention of the author to some experiments upon the same subject published by him in 1894.

Chemical Society, March 6.—Dr. E. Divers, F.R.S., vice-president, in the chair.—The slow oxidation of methane at low temperatures, by Dr. Bone and Mr. R. V. Wheeler. Much controversial matter has been published on this subject, the point in dispute being which of the two constituents of marsh gas, viz. carbon and hydrogen, undergoes oxidation first when the gas is burned in an insufficient supply of oxygen. The authors find that methane between 300° and 400° C. burns simultaneously to carbon monoxide and water, small quantities of carbon dioxide being also formed, probably as the result of a secondary reaction.—Isomeric additive compounds of dibenzyl ketone and deoxybenzoin with benzal-*p*-toluidine, *m*-nitrobenzalaniline and benzal-*m*-nitraniline, iii., by Dr. F. E. Francis.—These additive compounds exist in three modifications, differing in melting point and other physical properties, and are thus easily separable one from another.—Mesoxalic semi-aldehyde, by Messrs. Fenton, F.R.S., and Ryffel. When tartaric acid is treated with gaseous chlorine in presence of ferrous salts it undergoes oxidation, forming the semi-aldehyde of mesoxalic acid, which can be isolated in the form of its osazone and dioxime.—The action of hydrogen peroxide on carbohydrates in presence of ferrous salts, by Messrs. Morell and Crofts. In this reaction, glucose, mannose, lævulose and arabinose are oxidised to their corresponding osones.—*m*-Nitrobenzoyl camphor, by Dr. M. O. Forster and Miss F. M. G. Micklethwait. This substance has been prepared by the action of nitric acid on benzoyl camphor. The most interesting feature exhibited by it is that it only exists in the enolic form, whilst benzoyl camphor occurs in both ketonic and enolic modifications, camphor itself being only known in the ketonic form.—The Cloëz reaction, by Dr. Chattaway and Mr. J. M. Wadmore. When cyanogen chloride or bromide reacts with sodium ethoxide, urethane and triethylcyanurate are formed. This reaction is, at first sight, inexplicable if the formula C:N.Cl be assigned to cyanogen chloride, but the authors suggest that the latter reacts first with the alcohol, forming an ethyl iminochlorocarbonate, which in secondary changes gives rise to the products mentioned above.—The picrimidothiocarbonic esters, by Mr. J. C. Crocker. The author describes the products obtained when picryl chloride reacts with ammonium thiocyanate.—Robinin, violoquercitrin, myrticolorin and osyritrin, by Mr. A. G. Perkin. The author finds that myrticolorin, a quercetin glucoside, is identical with osyritrin.—The nitration of *sym.* trihalogen anilines, by Dr. Orton. When the aniline operated upon contains a bromine atom in the para-positions relative to the amino-group, it is replaced by a nitro-group. The similar chlorine substituted anilines do not undergo this replacement.—Some *sym.* nitrochlorobromanilines and their derivatives, by Dr. Orton. A description of the products obtained in the course of the foregoing investigations.—The resolution of pheno-α-aminoheptamethylene into its optical merides, by Prof. F. S. Kipping, F.R.S., and Mr. A. E. Hunter. This base undergoes de-racemisation when it is converted into the racemic *d*-tartrate and the latter is fractionally crystallised from water containing tartaric acid.

Linnean Society, February 20.—The Rev. T. R. R. Stebbing, F.R.S., in the chair.—On behalf of Mr. G. M. Thomson, of Dunedin, N.Z., the secretary exhibited a series of photographs of New Zealand flowers. In connection with the plants, some observations were made on the birds which visit them, *e.g.* the bell-bird or "korimako," *Anthornis melanura*, the grey warbler, *Gerygone flavirostris*, the pied fantail, *Rhipidura flabellifera*, and the yellow-breasted tit, *Petroeca macrocephala*. Of these, the first-named was observed to assist in the fertilisation of the native fuchsias, on quitting which the feathers of the head were seen to be stained with the bright

blue pollen of the flowers. A favourite nesting-site of the tit, *Petroeca macrocephala*, was said to be immediately under the head of the ti-tree, *Cordyline australis*, a good photograph of which was likewise exhibited.—A paper was read by Dr. J. E. Duerden on the internal structure and histology of *Bunodeopsis globulifera*, Verrill, a West-Indian sea anemone, which he had previously described as new (in a paper on the Jamaica Actiniaria published in 1898) although without bestowing any specific name. Prof. Verrill had since described it under the name *Bunodeopsis globulifera*, but his description was limited to an account of the external characters. Dr. Duerden now described in detail the peculiarities of its anatomy and minute structure.—Mr. B. Daydon Jackson, in a report on the botanical publications of the United Kingdom as a part of the "International Catalogue of Scientific Literature," gave the history of botanic bibliography from the time of Linnæus, mentioning the admirable catalogue by Dryander of Sir Joseph Banks's library and passing on to the Royal Society's "Catalogue of Scientific Papers," at present consisting of eleven volumes, ranging from 1800–1883, the last seventeen years being in course of compilation. The genesis of the "International Catalogue of Scientific Literature" was then briefly described and the means adopted for the collection and classification of titles given. The Linnean Society had contributed the titles of papers and books issued within the United Kingdom, amounting to about 2300, and the first part of the volume devoted to botany for 1901 was now in the hands of the printers for early publication.—A paper by Miss Lettice Digby was read on her behalf by Mr. J. E. S. Moore, on the structure and affinities of some Gastropoda from Lake Tanganyika belonging to the genera Chytra and Limnotrochus, the paper being based on material which formed part of Mr. Moore's African collections. The external features, nervous system and viscera were described in detail and the affinities of the species considered.

Zoological Society, March 4.—Mr. William Bateson, F.R.S., vice-president, in the chair.—Mr. E. N. Buxton gave an account, illustrated by lantern slides, of his recent sporting-expedition to the Egyptian Soudan, in the course of which he traversed the route along the White Nile between Khartoum and Fashoda. Mr. Buxton exhibited a series of photographs of mammals and birds taken from living specimens. Among these were views of the white-eared kob (*Cobus leucotis*) and the tiang (*Damaliscus tiang*).—Dr. H. Lyster Jameson read a paper on the origin of pearls. The author's observations referred especially to *Mytilus edulis*, the common mussel. The pearls were found to be due to the presence of parasitic Distomid larvæ, which entered the subcutaneous tissues of the mussel and became surrounded with an epidermal sack similar in its characters to the outer shell-secreting epithelium of the mantle. If the Distoma died in the sack it became calcified, and formed the nucleus of a pearl, the pearl arising, like the shell itself, from the calcification of the cuticle of the epithelial cells. The parasite sometimes migrated out of the sack, in which case the nucleus of the pearl was inconspicuous. Dr. Jameson had investigated the life-history of this parasite, and found that it arose as a tailless Cercarian larva, in sporocysts, in *Tapes decussatus* and *Cardium edule*. He had succeeded in infecting mussels from Tapes in an aquarium. The adult stage of this parasite was apparently *Distoma somatinae*, Levinsen, which occurs in the intestine of the eider duck, and which the author had found in the scoter or black duck (*Œdemia nigra*). The complicated life-history of the parasite, and the absence of organs of locomotion in the Cercaria-stage, sufficed to account for the anomalous and hitherto inexplicable distribution of pearl-bearing mussels. Dr. Jameson had found that pearls were caused by similar parasites in several other species of Mollusca, including some of the pearl-oysters; and he believed that the artificial infection of the pearl-oysters could be effected in a similar manner to that which he had found successful in the case of the common mussel. When this was achieved the problem of artificially producing pearls would be solved.—Dr. P. L. Sclater enumerated the species of parrots of which specimens were contained at the present time in the Society's collection—109 in all—and made remarks on some of the rarer species.—Mr. G. T. Bethune-Baker read a paper entitled "A Revision of the Amblypodian Group of Butterflies of the Family Lycænidæ." The author was of opinion that the whole of the species of this group could be conveniently relegated to six genera—viz., Amblypodia, Iraota, Surendra, Thaduka, Mahathala and Arhopala—and that it was useless to split up the genera further, as had been attempted by some entomologists.—A communication from Mr. Martin Jacoby contained the descriptions of sixty-three new species of Coleoptera of the family Halticidæ from Central and South America.

Geological Society, February 26.—Prof. Charles Lapworth, F.R.S., president, in the chair.—On some gaps in the Lias, by Mr. Edwin A. Walford. The author's endeavour is to prove gaps in the stratigraphical succession of the Lias, involving the removal of zones or parts of zones, and also to prove palæontological gaps by the abrupt appearance of many new genera of Mollusca.—On the origin of the river-system of South Wales, and its connection with that of the Severn and Thames, by Mr. Aubrey Strahan. The southerly courses of some rivers from the Usk to the Ogmore are described, and shown to be independent of both the east-and-west folding and the north-north-westerly faulting of the rocks on which they lie. Farther west the drainage-system takes a different direction, the rivers coinciding so closely with a set of west-south-westerly disturbances as obviously to have been determined in direction by them. Of the three systems of disturbance alluded to, the east-and-west (Armorican) folding was pre-Triassic; it marks a period of compression with impulse from the south, and though it reached great intensity in Devon, Somerset and South Wales, it died away in Central Wales. The north-north-westerly (Charnian) faulting, though partly of pre-Triassic age, was renewed in post-Eocene times, and is manifested over much of the British Isles. It marked periods of relief from pressure, and of subsidence. The west-south-westerly (Caledonian) folding was the latest; it marked a period of compression, with impulse from the north, and displayed greater energy in Central than in South Wales. It gave rise to a series of subsidiary disturbances in the latter region, and initiated and controlled the river-system. The ignoring by the rivers of the structures due to the earlier disturbances is attributed to the Palæozoic areas having been overspread by Upper Cretaceous rocks at the time of the initiation of the river-system. The eastward course of the Upper Severn is attributed to the upheaval of a main axis (now the main water-parting) in Central Wales. Its deflection to the south and south-west was due to the formation of an anticline in the Chalk, which must have been parallel to, but a little west of, the present Chalk-escarpment, and which was parallel to, and contemporaneous with, the Caledonian disturbances in Wales. This anticline, acting in combination with the Armorican folding displayed in the London and Hampshire basins, initiated the systems of the Thames and Frome. Those systems were initiated in post-Oligocene and pre-Pliocene times, and the same age is inferred for the systems of South Wales and of the Severn.

MANCHESTER.

Literary and Philosophical Society, February 18.—Mr. Charles Bailey, president, in the chair.—Mr. R. L. Taylor read a paper on a modification of Rose's method of separating cobalt and nickel. In the original process described by Mr. Rose and improved by Mr. T. H. Henry, barium carbonate and chlorine (or bromine) were added to rather strongly acid dilute solutions of the two metals and allowed to stand, with frequent shaking, for from twelve to eighteen hours. The cobalt was precipitated as sesquioxide, while the nickel remained in solution. Mr. Taylor finds that if a neutral solution is used, the precipitation of the cobalt is complete in a few minutes, and that excellent quantitative results can be obtained. The retardation of the reaction which occurs when the solution is (as Rose and Henry used it) strongly acid at the outset, the author shows, is due to the free carbonic acid which is produced in the solution when the carbonate is added to the acid liquid. A similar retardation occurs in a neutral solution if carbon dioxide is first bubbled through it or if soda-water is added to it. Mr. Taylor recommends the process for the separation and detection of cobalt and nickel in the ordinary process of qualitative analysis. Either barium or calcium carbonate may be used (dry, precipitated, as usually sold, will do) with bromine water, and if no free acid is present at the outset, the cobalt is all precipitated in five minutes. On filtering, nickel can be readily detected in the filtrate by adding a little ammonia and ammonium sulphide. If there is any free acid present at the outset, it must either be boiled away or neutralised before adding the carbonate. Sodium carbonate may be used for neutralising, but then the free carbonic acid must all be boiled away, and the liquid cooled, before adding the carbonate and bromine water.—Mr.

D. L. Chapman described some experiments which have been carried out, in conjunction with Mr. F. A. Lidbury, principally for the purpose of discovering whether Faraday's law may be considered as applying to gases. The electric discharge was passed through water vapour, and the separation of oxygen and hydrogen which took place was found to be from two to three times as great as that which occurred in a voltameter placed in the same circuit. The results are, therefore, inconsistent with the view that the phenomenon is essentially electrolytic.

February 25.—Mr. C. Bailey, president, in the chair.—Dr. Henry Wilde, F.R.S., delivered the Wilde lecture, his subject being "The Evolution of the Mental Faculties in Relation to some Fundamental Principles of Motion."

DUBLIN.

Royal Irish Academy, February 24.—Prof. R. Atkinson, president, in the chair.—Prof. F. T. Trouton read for Prof. W. Ramsay, F.R.S., a paper on the molecular surface energy of some mixtures of liquids. The liquids with which the determinations were made were mixtures of carbon bisulphide and chloroform, ethylene dibromide and chlorobenzene, toluene and acetic acid, ethylene dibromide and acetic acid, ethyl alcohol and benzene, ethyl alcohol and chloroform. Mixtures in proportions varying by about 10 per cent. each step were prepared and the surface tension determined in each case at several temperatures. From these it was sought to adduce information as to the state of molecular aggregation in the mixtures by calculating the mean molecular weight in each case given by assuming that the relation $\gamma(Mv)^{\frac{2}{3}} = k\tau$ holds good for mixtures. These determinations are given in the paper in the form of tables.—Prof. John Joly, F.R.S., read a paper on solvent denudation in fresh water and sea water." The experiments are comparative: on basalt, orthoclase, obsidian and hornblende. It is found that the rate of solvent denudation unaccompanied by attrition in sea water is very much faster than in fresh water, contrary to what is generally inferred from the experiments of Daubrée.

EDINBURGH.

Royal Society, February 3.—Lord M'Laren in the chair.—Mr. James Russell read a paper on magnetic shielding in hollow iron cylinders, the magnetising force being transverse to the axis of the cylinder. The field within the cylinder was measured inductively by means of a rotating coil in connection with a ballistic galvanometer. Two different iron cylinders were experimented with, and the cylinder could, if desired, be magnetised circularly by means of a coil wound round it parallel to the generating lines. The general conclusions are as follows:—(1) When no other magnetising force is acting than that due to the transverse field increasing by increments from zero, the shielding ratio diminished by unity is proportional to the ratio permeability (B/H) and not to the differential permeability (dB/dH). In descending fields the theoretic conditions are not fulfilled. (2) When a circular magnetising force is acting upon the iron cylinder in addition to that due to the transverse field, the order and manner in which the one field is superposed upon the other affects the shielding ratio to an enormous extent, and the conclusions arrived at are not in harmony with the investigations of Stefan and Du Bois (see *Electrician*, vol. xl. p. 654, 1898). When the circular magnetisation is superposed upon a pre-existing magnetisation due to the transverse field, the shielding ratio diminished by unity is proportional to the differential permeability as impressed upon the iron by the circular field. It attains a maximum for comparatively low values of this field and then falls off towards an asymptotic minimum. When the circular field is applied first, the shielding ratio becomes distinctly reduced in value, and becomes still further reduced if the transverse field is subjected to repeated reversal. On the other hand, repeated reversal of the superposed circular field increases the shielding ratio so long as the values of dB/dH are high. The paper contained many other results of interest. Prof. Schäfer, in a note on the existence within the liver cells of channels which can be directly injected from the blood-vessels, referred to the recent work of the Drs. Fraser and Dr. Browicz, and then drew attention to the fact that in one of the slides in the possession of the physiology department of the Edinburgh University the existence of these channels was clearly indicated. The slide was prepared in 1886 for Prof. Rutherford by Dr. (now Prof.) Carlier, but though Dr. Carlier drew Prof. Rutherford's attention to it at the time, no further notice was taken of it.—Dr. D. F. Harris, in a paper on functional inertia a property of protoplasm, contended that functional or metabolic inertia is that property of living matter in virtue of which it tends to remain in the functional *status quo ante*. It is of two kinds, katabolic and anabolic, according as it is katabolism or metabolism that persists in spite of stimuli tending to alter the metabolic phase. It was shown to express itself under very different categories — biochemical as "latent period," "refractory period" (physiological insusceptibility), as rhythm, or as accompanied by consciousness. Thus functional inertia is the physiological counterpart or antithesis of irritability or affectability. Its recognition as a property of protoplasm enables us to correlate a very large number of different phenomena of both animal and vegetable life having apparently nothing else in common.—In a paper on functional inertia of plant protoplasm, Mr. R. A. Robertson gave further illustrations of Dr. Harris's views. The phenomena of latent periods in stimulation by gravity, heat, contact, injury, are expressions of the anabolic phase of the inertia; those of the periods of activity after inhibitory stimulation—as when protoplasmic movement is inhibited by high temperature, sunlight, or absence of oxygen, assimilation by cold, desiccation or darkness, growth in length by light, &c.—indicate the katabolic phase of inertia. Functional inertia finds expression in the existence of stimulatory limits, periodicity of growth and movement, and in the phenomena of polarity, and so on. It appears as a physiological insusceptibility in photochemical induction and elsewhere. In virtue of it protoplasm can be educated and new characters acquired. Its time value varies from a few seconds to hours and may be artificially extended to days; its amount may be infinite in respect of a single stimulus of any degree of intensity, but relatively small (as in the case of a dry seed) for a combination of simultaneously acting stimuli.

PARIS.

Academy of Sciences, March 10.—M. Bouquet de la Grye in the chair.—Preparation and properties of a new hydride of silicon, by MM. H. Moissan and S. Smiles. Magnesium silicide having approximately the composition $SiMg_2$ was treated with dilute hydrochloric acid, and the escaping gas, which was spontaneously inflammable and consisted largely of hydrogen, passed through a U-tube cooled down to the temperature of liquid air. A solid substance separated out in the cooled tube, which partially boiled off on allowing the temperature to rise. The volatile portion was found to be ordinary hydrogen silicide, SiH_4, the remaining liquid, which boiled at 52° C., proving to be a new compound of the composition Si_2H_6, analogous to ethane. The most remarkable property of this new compound is that of catching fire spontaneously in the presence of air at the ordinary temperature, and if a small quantity of the liquid is introduced into a large volume of hydrogen, the latter also acquires the property of becoming spontaneously inflammable in air.—The conditions of vegetation of vineyards giving high yields, by M. A. Müntz. By systematic analyses of the soil, manure added, and the amount of sugar produced in the grape, the author has been able to correlate the amounts of nitrogen, phosphoric acid and potash used in the production of one kilogram of alcohol from the fermented grapes. It is found that vines giving high yields require larger amounts of fertilising materials, but that the latter do not increase in proportion to the amounts of sugar elaborated.—On the extension of the theorem of Lagrange to viscous fluids, by M. P. Duhem.—On glycosuria due to asphyxia, by MM. R. Lépine and Boulud.—M. Winogradsky was nominated a correspondant in the section of rural economy in the place of the late M. Demontzey.—Observations of the sun made at the Observatory of Lyons with the Brunner 16 cm. equatorial during the third quarter of 1901, by M. J. Guillaume. The results are expressed in three tables, showing the number of spots, the distribution of the spots in latitude and the distribution of faculæ in latitude respectively.—A theorem on trigonometrical series, by M. H. Lebesgue.—On factorial series, by M. J. C. Kluyver.—On the cohesion of liquids, by MM. Leduc and Sacerdote. A new interpretation is given of an old experiment in which the weight required to pull away a plane glass surface from a liquid is regarded as a measure of the cohesion of the liquid. In reality the cohesion of the liquid has nothing to do with the effect.—The electromagnetic theory of the aurora borealis and the variation and perturbations of terrestrial magnetism, by M. Charles Nordmann. It has been shown that there is a close relation between the spectrum of the aurora and

that of the light round the kathode of a tube containing oxygen or nitrogen. The author concludes that the aurora borealis is a kathode phenomenon produced in the rarefied layers of the upper atmosphere by Hertzian waves emanating from the sun. The theory of Arrhenius is adversely criticised.—On a new application of optical observations to the study of diffusion, by M. J. Thovert. The optical method described in a previous paper is applied to the determination of the diffusion constants of solutions of the acids, alkalis and some salts. The numbers obtained for the salts accord well with those calculated from electrolytic data by Nernst's diffusion theory; for the acids the observed numbers are smaller than the calculated.—Remarks on a recent note of MM. Nagoaka and Honda relating to the magnetostriction of nickel steels, by M. F. Osmond.—Study of the transformations of steels by the dilatometric method, by MM. Georges Charpy and Louis Grenet. Two transformations can be observed in the iron-carbon alloys by the dilatometric method: the one brusque, produced at 700° C., with contraction of volume, corresponding to the absorption of heat observed at the critical point a_1 in the pyrometric method; the second a more gradual one, taking place at a temperature near that of the critical point a_3 as determined by the pyrometric method.—The action of hydrogen peroxide on oxide of zinc, by M. de Forcrand. The experimental results of the author lead to the conclusion that zinc can exist in three states of peroxidation, Zn_3O_5, Zn_4O_7 and ZnO_2.—On a new phosphate of soda, by M. H. Joulie. Ordinary sodium phosphate is mixed with phosphoric acid until it is neutral to litmus. On concentration, crystals of the new salt separate out; they possess the composition $Na_3H_3(PO_4)_2$. It is pointed out that this salt presents certain advantages from the therapeutic point of view.—Reduction of orthonitroazoic colouring matters: production of substituted derivatives of phenyl-pseudo-azimidobenzene, by MM. A. Rosenstiehl and E. Suais.—On the variation of rotatory power in the esters of stable lævorotatory borneol, by MM. J. Minguin and E. Grégoire de Bollemont.—On the separation of galactose and glucose by the *Saccharomyces Ludwigii*, by M. Pierre Thomas. Glucose is readily fermented by this yeast, but galactose is not attacked. Details are given of the best mode of carrying out this separation, which affords very good yields.—The study of the lactic fermentation by the observation of the electrical resistance, by MM. Lesage and Dongier.—The evolution of branchial formations in the adder, by MM. A. Prenant and G. Saint-Remy.—Study of a liver-wort with thallus inhabited by a fungus, by M. J. Beauverie.—On a fossil Parkeria, by M. B. Renault.—Researches on the modifications of the blood and serum preserved aseptically by heating. The lipolytic function of the blood, by MM. Maurice Doyon and Albert Morel.—Volume in urology. The volume type and the dynamical coefficient, by M. J. Winter.—Experimental researches on the biological life of a xiphopage, by MM. N. Vaschide and Cl. Vurpas.

GÖTTINGEN.

Royal Society of Sciences.—The *Nachrichten* (physico-mathematical section), part iii. for 1901, contains the following memoirs communicated to the Society:—

November 8, 1901:—W. Voigt: The electron-hypothesis and the theory of magnetism. A. Auwers: Right ascensions of 792 stars observed with the meridian instruments of the Göttingen Observatory in the years 1858 and 1859.

December 21, 1901:—V. Rothmund: On the formation of calcium carbide.

The accompanying "business number" contains an interesting account by the presiding secretary of the proceedings in connection with the 150th anniversary of the Society, celebrated in November last.

DIARY OF SOCIETIES.

THURSDAY, MARCH 20.

ROYAL SOCIETY, at 4.30.—Development of the Layers of the Retina in the Chick after the Formation of the Optic Cup: J. Cameron.—On a Peculiarity of the Cerebral Commissures in certain Marsupialia, not hitherto recognised as a Distinctive Feature of the Diprotodontia: Prof. G. Elliot Smith.—The Classification of the Elements: Prof. H. E. Armstrong, V.P.R.S.—Persulphuric Acids: Prof. H. E. Armstrong, V.P.R.S., and Dr. T. Martin Lowry.—On a Throw-Testing Machine for Reversals of Mean Stress: Prof. Osborne Reynolds, F.R.S., and J. H. Smith.—On the Equilibrium of Rotating Liquid Cylinders: J. H. Jeans.—A Portable Telemeter, or Range-finder: Prof. G. Forbes, F.R.S.

LINNEAN SOCIETY, at 8.—Electric Response in Ordinary Plants under Mechanical Stimulus: Prof. J. C. Bose.—On the Fruit of *Melocarina bambusoides*, Trin., an Exalbuminous Grass: Dr. O. Stapf.—On Malacostraca from the Red Sea Collected by Dr. H. O. Forbes: Messrs. Alfred O. Walker and Andrew Scott.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Problems of Electric Railways: J. Swinburne and W. R. Cooper.

FRIDAY, MARCH 21.

ROYAL INSTITUTION, at 9.—Recent Developments in Colouring Matters. (In English): Prof. Otto N. Witt.

INSTITUTION OF MECHANICAL ENGINEERS, at 8.—Fencing of Steam and Gas-Engines: H. D. Marshall.—Fencing or Guarding Machinery used in Textile Factories: S. R. Platt.—Protection of Lift-shafts, and Safety Devices in connection with Lift-Doors and Controlling Gear: H. C. Walker.—Guarding Machine Tools: W. H. Johnson.

EPIDEMIOLOGICAL SOCIETY, at 8.30.—Infantile Mortality in the Tropics: Dr. Daniels.

SATURDAY, MARCH 22.

ROYAL INSTITUTION, at 3.—Some Electrical Developments: Lord Rayleigh, F.R.S.

ESSEX FIELD CLUB (Essex Museum of Natural History, Stratford), at 6.30.—Annual Meeting. The Presidential Address will be delivered by Prof. Meldola, F.R.S., on The Coming of Age of the Essex Field Club, a Record of Local Scientific Work, 1880–1901.

MONDAY, MARCH 24.

INSTITUTE OF ACTUARIES, at 5.30.—The British Offices Life Tables, 1893; an Investigation of the Rates of Mortality in different Classes of the Assurance Experience, and of the resulting Net Premiums and Policy Reserves: T. G. Ackland.

TUESDAY, MARCH 25.

MINERALOGICAL SOCIETY, at 8.—The Petrology of British East Africa: Notes on the Rock-specimens collected by Prof. J. W. Gregory and Sir Harry Johnston respectively: G. T. Prior.

INSTITUTION OF CIVIL ENGINEERS, at 8.—The Greenwich Footway-Tunnel: W. C. Copperthwaite.—Subaqueous Tunnelling through the Thames Gravel, Baker Street and Waterloo Railway: A. H. Haigh.

A GERMAN VIEW OF ENGLISH SCHOOLS.

Der Naturwissenschaftliche Unterricht in England, insbesondere in Physik und Chemie. Von Dr. Karl T. Fischer. Pp. viii + 94. (Leipzig: Teubner and Co., 1901.) Price mk. 3·60.

THIS work treats of the various methods of, and provision for, teaching science, principally physics, in English schools. The author, after a preliminary visit to this country in 1897, was commissioned by the Bavarian Government to spend six months in studying the efforts made in England to introduce the study of science into schools. The variety of organisation which exists in England lends itself to educational experiments, and the preference for boarding-schools, where the efforts of the teachers are not interfered with by parental care, often eliminates a disturbing cause which might influence the results of the experiment. It is remarked, that in comparison with continental schools, the school fees are enormously high; but, without reference to the necessities of the case, the parent is often solaced and his pocket relieved by the bestowal of scholarships upon boys capable of excelling in examination.

The author appears to have sampled the schools fairly well. Besides visiting many universities and university colleges, he saw the Manchester Municipal Technical School; the Technical Institutes at Salford, and at Birmingham and Dublin; the Girls' Central Foundation School; schools at York, Darlington and Leeds; the St. Dunstan's College, Catford Bridge; Tunbridge School; Clifton College, and Harrow; besides some smaller schools. The system of object lessons is described, and details of the syllabuses for elementary physics and chemistry in elementary schools are set forth. Similar details are given of the teaching in preparatory schools and in typical grammar schools, as well as in public schools. The work of the London polytechnics is sketched. The author contrasts the German technical institutes with these, not wholly to the advantage of the English institutions. The statistics of the Science and Art Department are quoted, as are also its programmes.

The author has been wrongly informed that chemical laboratories in Great Britain have only of recent years been open to students. Prof. Thomas Thomson's chemical laboratory at Glasgow and Prof. Hope's laboratory of "natural philosophy" at Edinburgh were available at the beginning of the nineteenth century; and in England, Prof. Turner's laboratory was advertised at least as early as 1834. The laboratory of the Pharmaceutical Society is of about the same age.

After quoting from Helmholtz, Tyndall, the late Prince Consort and Huxley, it is suggested that the effect of classical studies is to influence the imagination, that of science the understanding, and that the latter is to be awakened only through experimental acquaintance with the facts of science; and in England, in contrast with most German schools, the end is gained by laboratory practice. This, of course, can be achieved only by making each student carry out the same operation at the same time; in other words, by laboratory drill, and the system has been carried to a high pitch of perfection. In many schools the so-called "heuristic" method is adopted, according to which children make discoveries under leading strings. A typical syllabus of the methods of inducing children to make such discoveries is given in full. It would be, perhaps, too much to ask that those who inculcate such methods should first have practised what they preach; but when it is remembered that it took the best part of two centuries, and the ablest minds of many nations, to discover the composition of air and of water, it is doubtless hardly to be expected that either young children or their teachers would gain much by this method of teaching and learning. The training of science teachers in England is described, and the methods of South Kensington and its imitators are treated of; the cost of apparatus, too, receives ample notice.

Recent criticism of the "heuristic" system in England is, as proved by ample quotations, not favourable; those who have tried it have had to modify it greatly. Indeed, in the reviewer's opinion (who committed an indiscretion in the same direction in 1882), the conclusions are necessarily drawn from far too restricted premisses. While *very* clever lads are interested, they do not, nevertheless, gain the advantages which might be expected from a consideration of the experiments which they make; and the average student of seventeen or eighteen is simply a machine and his mind a fog—all that he learns is manipulation, and even that is faulty.

The conclusion of the book is an attempt to indicate what the English think of the German system and what the Germans hold concerning English methods. For the last, it might have been well to have waited for a second edition, after the present one had made the Germans better acquainted with recent developments of scholastic attempts in England; for, on the whole, the author has given a very unprejudiced and correct account of his subject.

But many Germans have already made up their minds on the general question. One often hears a German professor say that he prefers a pupil to come to him ignorant of the subject he has to study, but well drilled in classics and mathematics. Indeed, a prominent English teacher of science confessed to Dr. Fischer that he preferred to teach boys trained on the "classical side," who had specialised in science later, to those trained exclusively on the modern side; the words are quoted in English: "They prove better, being of higher standard in character." As the late Prof. Fitzgerald once remarked, in arguing in favour of the retention of Latin in schools: "There is no other subject in which it is possible to set so many small problems all within the reach of a boy's intellect." But the problems of science, unless they are confined to those of mechanics, in the solution of which mathematics may be made to bear its important share, are too subtle for the young mind, as indeed the teacher would find who endeavoured to instruct a class in ethics or in jurisprudence, both subjects well deserving of man's attention. One must ask—to what end is all this energy directed? Is it to educate citizens or discoverers? If the former, then the

reviewer ventures to suggest that better materials exist than such scraps of science which form the pabulum of the average science master, and are reproduced in wearisome iteration in the scores of elementary text-books which it appears to pay our publishers to bring out; if the latter, it must be confessed that our German neighbours, who have not as yet adopted such methods, are more prolific in quantity of research, at least, than we. W. R.

CHEESE-MITES.

British Tyroglyphidae. By Albert D. Michael, F.L.S., F.Z.S., F.R.M.S., &c. Vol. i. (London: Printed for the Ray Society, 1901.)

IF the world sometimes knows little of its greatest men, it often knows still less of its most familiar fellow-creatures. To work out the story of a cheese-mite with proper completeness is a task which many might undertake in a spirit of condescension, only to retire from it helplessly disconcerted. Yet none need be deterred from the enterprise by want of specimens, for though the Tyroglyphidæ are but one family out of many in the host of the Acarina, they produce a population absolutely beyond estimate in numbers. Together with the few species which, in accordance with the family name, are really "sculptors of cheese," there are many others that use a quite different diet. On learning that they like senna as well as dried figs, cantharides as well as French plums, that they are partial to decaying mushrooms, that they eat hay with equine avidity and dote on rush-bottom chairs, the reader will infer that they have a fine catholicity of taste in which our prejudiced palates can only partially follow them. The ubiquity of these minute animals betrayed one experimentalist into believing that he had been able to create them by electricity. From such points of general interest with which Mr. Michael enlivens his introductory chapter, he proceeds to aspects of his subject which have a fascination for many who care nothing for the subject itself. There is seldom a group of animals, however low in popular esteem, that does not occupy a considerable space in the literature of science. Still more rarely, perhaps, has any group escaped all erratic movements in the course of classification. A clear-sighted guide, himself in the forefront of existing knowledge, renders first-rate service to scientific progress in general when for his special branch he shows how the explorers have opened the road for their successors or how they have obstructed it. The path of investigation is ever liable to be deflected, arrested or reverted by the failures of the infallible, the specious finality of those who attempt to do too much, and the slovenly ineffectiveness of those who are content to do too little. Notwithstanding the invariable courtesy with which Mr. Michael writes of his predecessors and fellow-workers, one may perceive from the bibliographical survey here, as well as from that in his earlier work on the British Oribatidæ, that the study of mites has not been wholly free from "regrettable incidents." Immortality at any price seems to be the watchword of those who describe species in such a fashion that no succeeding naturalist can make out what animals precisely were intended by the descriptions. In discussing the common properties of a group and the broad lines of its classification, less harm is done by the careless and the muddle-headed, because their mistakes in these departments can eventually be corrected, and as when thieves fall out honest men come by their own, so sometimes from a conflict of errors truth finds a chance of emerging.

In the ordinary doctrine of text-books the Acarina are distinguished from other arachnids as having, not only the head and thorax coalesced, but the cephalothorax itself completely fused with the abdomen. In the present volume, however, it is pointed out that there is very frequently found a constriction or furrowing of the body behind the second pair of legs. This is held to justify the application of the term abdomen to the part of the organism behind the constriction or furrow. But such an allotment of the first two pairs of legs to the cephalothorax and of the last two pairs to the abdomen would surely be equivalent to severing the Acarina from the arachnids altogether. From segmental demarcation between the second pair of legs and the third nothing more can properly be inferred than that one part of the thorax is more intimately fused with the head and the other part with the abdomen. It is quite true, as Mr. Michael argues, that the Malacostraca are abundantly supplied with abdominal limbs, but these are always sharply distinguished in character from the thoracic appendages, unless in some unique monstrosity. In the case of the Acarina, no perceptible advantage is gained by a theoretical transfer of limbs from the thorax, on which they are normal, to the abdomen, where they would be anomalous.

On other subjects Mr. Michael is much more convincing. His whole discussion of the acarine "nymph" is highly interesting and worthy of admiration. While the larva perhaps never, and certainly hardly ever, has more than six legs, the nymph like the imago or adult has normally eight. The nymphal stage extends from the acquisition of the full number of legs to the last exuviation. There is, however, one group in which it is still uncertain "whether the nubile female is a nymph or an adult." Here the difficulties of investigation are very great, the little creatures being found usually in numbers on the feathers of birds, and, as they will not live away from the host, the isolation necessary for observing the whole series of their transformations seems practically impossible to arrange. Nevertheless, the account given of the genera Hypopus and Homopus shows how difficulties can be made to yield to untiring patience, such as both Mr. and Mrs. Michael evidently combine with other valuable accomplishments. Opinions upon the supposed genera just mentioned have been various and fluctuating. The final result is to establish clearly that the two names in question are not of generic value. They simply refer to a particular stage in the life-history of the Tyroglyphidæ. For designating this stage they are still valid, although they do not add to the musical charm of a sentence by making us speak of hypopial nymphs and homopial hypopi. The difference is concisely expressed by the statement that the hypopus is homopial when "it adheres to its temporary host, not by suckers, but by holding one or more of the hairs of the host between special plates on the ventral surface of the parasite." Suckers facilitate adherence to smooth chitinous insects

and other polished surfaces; claspers are used upon hairy mammals, such as moles and squirrels. A strange part of the business is, that by no means all the young nymphs of a species change into hypopi, and yet that those which do change include both sexes. How little they resemble the form from which they emerge and to which they return is indicated in the opinion entertained by one writer, that the hypopus was a parasite which entered the nymph and ate it up, all but the skin. To accuse it of such ravaging propensities is peculiarly unkind, since it has but a rudimentary mouth and there is little reason to believe that it feeds at all. The innocent purpose of the transformation seems to be merely to secure distribution of the species by varied contrivances for adhesion to moving objects. Acarids themselves are a slow-moving race. Unaided they can travel neither fast nor far, though a Gamasid can traverse four inches in a minute. On the other hand, they multiply with a fertility so portentous that any measures for dispersing the surplus population must be welcome in their commonwealth. But guileless as the hypopi are individually, a heart of stone would be touched at the affliction they cause in mass to the industrious ant. That long-suffering tribe is said to find some twelve or thirteen hundred species of other animals willing to share, or at any rate that are present among, the amenities of its civilised nests. One of these species is the cheese-mite *Tyroglyphus wasmanni*, and Wasmann, after whom it is named, found that a single ant might be infested by fifty, or a hundred, or a thousand, or even thousands of the hypopi, not feeding upon it, but clogging all its organs, so that it could neither talk with its antennæ, nor feed with its mouth, nor walk with its feet, nor clean itself with its combs, till the poor creature, against its will made sordid and useless, would fall into a lethargy and die.

Mr. Michael has long held a foremost place among acarologists. It may be confidently assumed that his reputation, high as it is, will be advanced by the present volume. Though the Tyroglyphidæ are comparatively simple in structure, his skilfully drawn plates help us to understand much in them that is peculiar and to admire occasional features that are really beautiful. Notwithstanding the necessarily technical and systematic character of the work, so many suggestive and critical comments diversify the recital that it will be studied with pleasure by readers who are quite outside the limited circle of specialists. T. R. R. S.

OUR BOOK SHELF.

The Journal of the Royal Agricultural Society of England. Vol. lxii., 1901. Pp. cciv + 403. (London: J. Murray.)

IT is greatly to be regretted that the council of the Royal Agricultural Society has decided to publish the Society's journal in future as an annual volume. For fifty years the journal appeared twice in the year, and during the last eleven years it has appeared quarterly. The alteration now made is a very serious retrograde step. Not only is the space occupied by original articles and reports reduced to nearly one-half of that previously found in the *Quarterly Journal*, but the publication of new matter is now seriously delayed. We have in this country a sad lack of any provision for the publication of important agricultural papers. Besides the weekly agricultural newspapers, we have only the journals of our agricultural societies; these are small annual volumes, with the exception of the late *Journal* of the Royal Agricultural Society. This journal, with a circulation of 10,000 copies, has hitherto done something to provide the required means of publication. In it the majority of the reports by Lawes and Gilbert has appeared. Where could such reports be published now? The question is a very serious one, for it involves the ignorance or instruction of our agricultural readers; and an agricultural society could do nothing more useful than the regular and systematic publication of all work relating to the improvement of agriculture. The *Quarterly Journal* now issued by the Board of Agriculture does not attempt to discharge this function; it is principally confined to the publication of statistical matter and the results of experiments carried out with funds supplied by the Board.

The present volume contains much interesting matter. The long paper on English agriculture in the reign of Queen Victoria is full of facts worth recording, though some strange mistakes are made. What, for instance, was the Royal Chemical Society, founded in 1845 through the efforts of Johnston and Voelcker? The Chemical Society of London, to which the author probably refers, was, in fact, founded in 1841. The Society originated in London. At this time Johnston was a lecturer at Durham, and Voelcker was being educated in Germany, and did not join the Society until 1849! There is a very clear and concise statement by Prof. J. McFadyean on the evidence at present existing as to the relationship between human and bovine tuberculosis. This is a weighty utterance on a most important subject. The paper on English varieties of hops will be welcomed by hop-growers. The articles are followed by the usual reports of the Society's chemist, botanist and zoologist. The most notable result in the Society's experiments at Woburn is the immense effect produced by a dressing of lime in the barley-field; this application of lime has increased the produce by ammonium salts in one case by more than thirty bushels. An appreciative biography of Sir J. H. Gilbert is contributed by Dr. J. A. Voelcker.

R. W.

Selection of Subject in Pictorial Photography. By W. E. Tindall, R.B.A. Pp. 83. (London: Iliffe and Sons, Ltd., 1901.)

MANY of us who frequent photographic galleries or exhibitions have often been struck with the fact that, although a great amount of photographic skill has evidently been bestowed on the production of some particular print, yet in spite of this the effect is not at all pleasing to the eye, and the picture is not "a success." In many cases this is due to faulty composition, the photographer not having paid sufficient, if any, attention to the elementary laws governing this branch of the art. In photography, as in painting, there are many fundamental rules which must be followed to secure a pleasing effect, and the aim of the author of this book is to set out these points for the use of the photographer.

In a series of very instructive and interesting chapters, attention is directed to the composition of all kinds of subjects with which the photographer is likely to meet, and the difficulties peculiar to each class are described.

Further, the author does not restrict himself solely to describing the chief points in the composition of any one subject, but he illustrates them by means of paintings, drawings and photographs, which add greatly to the force of the text.

In conclusion, it may be stated that the author has given us a book which should prove of great service to those who require information on composition in pictorial photography, and a useful addition to the photographer's library.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Teaching of Mathematics.

MANY correspondents who hold views much like my own are angry that I should lend my countenance to the sort of reform in mathematical teaching which is now being so strongly advocated by the recognised teachers and by mathematicians. I beg to assure these friends that I am acting in a very consistent way, and I mean to help the reformers so long as they do me the honour to let me assist them.

My dearest wish is that Englishmen should prepare for the new phase in the struggle for existence which has so suddenly come upon the world. I believe that it has been growing for sixty years, that it is going to be very intense during the next twenty years, that it will be important for the next hundred years and that the weaker nations will have been completely defeated before the end of that time, before people in general recognise their foolishness in wasting coal. At Glasgow I was sneered at as thinking that all men were going to be engineers. Would to heaven that I could think of all young Englishmen as being fit to become engineers! I firmly believe that no nation will survive the coming struggle which does not equip itself with that thorough training in applied science which I call engineering. I do not expect to be believed by our schoolmen. They do not know, and they would not care much if they did know. The study of natural science has been discouraged by clerical schoolmasters and ecclesiastics, and men like Huxley worried themselves very vainly in consequence. But the time is quickly coming when, instead of the castigating rod of Huxley, we shall feel the stinging scorpions which fate provides for all men who set themselves to believe lies. There is just one chance for us; it has befriended the English people at several critical times, namely, that however foolish we may be, other nations may be as foolish or even more foolish still; and possibly our people may attend, in good time, to the sort of advice which they so usually laugh at.

I say that if even a small amount of knowledge of natural science and of scientific method could be given to our public men it would be a good thing. Now all influential Englishmen pass their youth and get what is fondly called education at the public schools and the two older universities. I have satisfied myself that the authorities of these institutions will steadfastly set their faces against any such large and radical reform as I have asked for; I was quite sure of this before I gave my address at Glasgow. It was only during the discussion that I began to get hope of any reform whatsoever in these institutions, and now I am sure that, not only is a small immediate reform really possible, but that this reform will increase as the years go on.

It is true that I was thinking of other universities, of other schools and colleges, but if any reform, however small, is possible in these great institutions, surely it is the duty of every lover of his country to help forward this movement. When one thinks that Clifford and Cayley and Sylvester and the other great mathematicians of the British Association Committee of 1873 advocated for English public schools the very reforms in geometrical teaching which are now being asked for, and that in most of the public schools the teaching is even more stupefying now than it was in 1873, one is not likely to be very sanguine. But I have satisfied myself that there is a power now behind the reformers which is very much more earnest and persistent than Clifford could rely upon; indeed, I am satisfied that the reformers have with them the good wishes of every thoughtful teacher of the whole country. And after all, would not even the smallest of reforms be exceedingly important in the public schools of England?

Eton and Harrow and Winchester and the rest, are they not great in every way? Oxford and Cambridge, what greater names are there than these among universities? These institutions in the past have educated the great men of England. I think I see immense faults in them, but when I compare them with all other schools of which I know anything, do I not know that in mental and bodily health their pupils are great in number and in quality? And if just now a time of strain is coming for which these institutions are quite unprepared, shall I sulk and say that because they will not do as I think they ought to do, then it is better that they should do nothing? To tell the truth, I think that our schools with a small reform will be equal to foreign schools even if these have every advantage that the latest notions in pedagogy can give them. Nevertheless, is it not rather the good material that comes to these schools for education than the schoolmasters of the schools that has our admiration? I feel myself that we are arming our people with bows and arrows when we might easily give them magazine rifles with telescopic sights. But surely, if it must be bows and arrows, and nothing better is possible, one is doing good by advocating the employment of the very best kind of bows and arrows.

I asked for a countenance from the mathematicians at Glasgow for a much more radical reform, not in the public schools and the two older universities—there I thought all reform impossible—but in the new universities, in all colleges where the study of natural science, and especially of applied science, is important. Although all the speakers were in favour of reform, quite half of them were out of sympathy with what I consider to be most essential. I know that they represent the great majority of the mathematicians and teachers of the country, and I should like again, however hopelessly, to explain my position to them. They refuse to attempt to look at things from my point of view. Their minds are beautifully in tune; what one scholar says, the mind of another responds to, but if anyone not a scholar of the orthodox type says anything, it is not heard at all, or only that part of the message is heard which is in tune with the receiving brain. My message must continue to seem to them very absurd if they make no effort to synchronise their mental apparatus with mine.

I assert that the orthodox logical sequence in mathematics is not the only possible one. I can imagine a sequence leading men of twenty-five to a proof of the axioms of Euclid; where it would start I do not know, perhaps in Berkeley's notions of sensation and that all matter and motion and shape are merely forms of consciousness. Surely every academic person will admit this as feasible. But he will not admit that there might be a thoroughly logical sequence starting with axioms which are now "proved" after many years of study, the notions underlying the infinitesimal calculus, for example; the notion that a map may be drawn to scale; the notions underlying the many uses of squared paper; the notion that decimals may be dealt with like ordinary numbers.

The swineherd Ho-ti and his son Bo-bo discovered the wonders of roast pork through the burning of their cottage, and they and their neighbours and every mandarin of China who studied the matter considered that it was absolutely necessary to burn a house down if one wanted roast pork. So the cult of house-burning arose in the land. But after many generations there came a sage of the name Pel-li, who pointed out to everybody that it was not necessary to burn houses, as a simple domestic fire was all that was needed. And he and his growing number of disciples were envied till a charge of impiety was brought against him. And of all the hundred accusers of Pel-li, all mandarins of high rank, every one was absolutely honest

and sure that it was really impious to roast pork without burning houses, and so Pel-li and his followers were crucified. If I were to tell my friends that I am Pel-li and that there is a very perfect parallelism between the two cases, they would laugh at the absurdity of such a statement, even if I made it from the cross. And yet, O mandarins, I say to you that you have brought against me the charge of impiety because you cannot imagine any other way of getting to the notions of the infinitesimal calculus than the way in which you yourselves arrived at them, and because I say that they are easier to take in than the axioms of Euclid.

Is it impossible, then, to imagine a different logical sequence from that in which one has been brought up? The very greatest difficulty which I meet with is in getting men to see that if a boy has practised measurement with a scale of inches and tenths of an inch he can understand decimals without a philosophical explanation. This fact, obvious to me, I have not been able to get believed in by any one teacher of arithmetic who plumes himself on his knowledge of the theory of teaching. Well, I go further and say that as an explanation is not necessary for a boy, to give him a grown-up explanation is a crime. Again, I like when dealing with quite easy arithmetic to make boys evaluate most complex formulæ, using all sorts of tabulated functions so that they may regard algebraic signs as a sort of shorthand. I cannot in a few words explain the wonderful mental value of this practice. My critics not only see no value in it, they look upon it with abhorrence. This is not through an effort of their reasoning; it is merely because the thing is strange to them, and, like the Dudley miner, they say, "'Ere's a stranger, Bill, let's 'eave a brick at him." If my critic has any kind of satisfying reason for his abhorrence I suppose it is because he thinks this new custom of mine resembles some most pernicious slipshod habits for which he is continually blaming his pupils—getting off propositions by heart and pretending one knows them; using a rule of arithmetic or dynamics in a mechanical way without understanding why; assuming that one understands a part of an investigation when one does not, and in all sorts of other fraudulent ways pretending to follow a logical sequence and degrading it. Now I also abhor these things. But what my students do is very different and is perfectly logical. They make no pretence of having proved anything, they are merely familiarising themselves with the shorthand of algebra, a thing that they cannot do too soon. If they get to look upon this as the A B C of mathematics they will not after many years of study feel proud of their mathematical knowledge when all they can do is to merely use formulæ in a text-book. Not long ago in an engineering journal the writer of a letter complained that he had been asked to evaluate the expression

$$a\epsilon^{-\alpha t}\sin(bt+g)$$

(being given the values of a, α, b and g) for several values of t. He said he had passed most difficult examinations and knew higher mathematics, but it was quite ridiculous that anyone should expect him to know so much. His anger was extreme. Now some of my students have evaluated things like this before they did any formal algebra at all, but they do not dream of calling it higher mathematics. Surely there is every good in letting a boy become familiar with all sorts of formulæ long before we lead him through the logical sequence which deals with such formulæ, just as we let a boy learn to use words before we teach him grammar or philology. But whether I am right or wrong, I do wish that my critics would try to see exactly what I advocate before they throw blame. The cock-shies that they fling their stones at have nothing in common with any part of my scheme.

I want it to be understood that I advocate a sequence as logical as the orthodox one, or rather, I should say, ever so much more logical, because in the orthodox sequence a boy is really unfamiliar with the ideas to which his so-called logic is applied. The usual sequence may be logical to a philosopher, but it is quite illogical to the average English boy.

I say that what is essential is that the student should be thoroughly familiar through experiment, illustration, measurement and every other possible method with the ideas to which he applies his logic. Also that the study should be of interest to him. I submit that the sequence which I recommend can really be made interesting to the average English boy, whereas the orthodox sequence is painfully uninteresting to him. One reason for this great interest lies in its immediate application to all sorts of actual problems such as he meets with in the study of natural science, and I do not care to hide the fact that there is a special interest which is due to the usefulness of the results of the study in the life-work that lie before him. If anybody cares he may misrepresent me here to any extent. Over and over again the academic person has been kind enough to sneer at my utilitarianism as if I were sacrificing the spiritual for the material, as if engineering were a thing of mere formula. On this I can add nothing to what I have already given in my British Association address and in my other papers. But if my critics only knew what wonderful regions of logical thought and high emotion are connected with the practical applications of natural science, if they had the respect which I confess to have for common things, they also might say as Heracleitus said of his kitchen with its pots and pans, "Here also are the gods." In his typical poem "Shop," Browning takes the college-common-room point of view. Heavens, what a sordid narrow point of view it is! The Bloomsbury bric-à-brac shopkeeper gets all the poet's scorn because he does not hate shopkeeping, because to him "shop was shop only." Does anybody imagine that Shakespeare could not have glorified the life of the shopman? But this poet, with all the arrogance of his caste, says, "I want to know a butcher paints, a baker rhymes for his pursuit." The moment a man has leisure he must escape from his trade! For my part, I believe that whatever a man finds to do he ought to do with all his might and with all love and devotion, or not attempt to do it at all. If he hates shopkeeping, let him give it up to someone else to whom shopkeeping is a perfect happiness. If Ruskin's influence over a man has been great enough to prevent his seeing the romance, the wonder of engineering, so that it is to him a mere trade by which he earns his bread and butter, in heaven's name let him give it up altogether and take to art criticism. For my lovely mistress, Applied Science, scorns a divided worship. It is disgusting to see young engineers who cannot compute, who know nothing of science, whose souls are not engrossed all the time with the greatness of their profession, who never think of their business after office hours, who think it all a mere matter of formulæ and tools. If they were fit for their work their lives would fill with happiness, and even the power to rhyme and paint and to create music might belong to them; but woe unto the nation whose shopkeepers scorn shopkeeping while they paint or fiddle; whose schoolmasters rely on cricket and a housemaster to do their proper business whilst they discuss Browning and the musical glasses. To make a man fit for, so that he may also love, his profession, is this a function to be scorned by schools and colleges? and am I to be sneered at as a utilitarian because I consider this a most important function of the schoolmaster?

Nobody has contradicted my statement that the orthodox method of cramming average boys with demonstrative geometry stupefies them and makes them hate mathematics all their life after. May I also point out that the beautiful philosophy of Euclid is also degraded, just as the literature of Greece and Rome is degraded, by our school methods. Is there anybody

who does not think of Euclid merely as a lower school subject? At the British Association discussion a great mathematician was astonished that I should ever have had to study the fifth book of Euclid. He said he was more fortunate, because he was never taught it. Well, I was never compelled to study it, but I took to it through mere affection such as my critic deems it his good fortune never to have experienced. What I regret is that any kind of demonstrative geometry was given me when a boy, but since it was given me I am glad to think that I had Euclid's philosophy undefiled. I even dipped into those books now never published—the seventh, eighth, ninth, tenth, and also the thirteenth, fourteenth, and the books added by some Greek author whose name I forget, the fifteenth and sixteenth. At the same time, I feel that if demonstrative geometry is to remain a school subject for the average boy, it is absolutely necessary to replace the second and fifth books by algebra. The view to which I hold most firmly of all my views about the teaching of mathematics is that demonstrative geometry ought never to be taught to boys at all; it ought never to be taught in schools. It is a higher university subject. Euclid's treatment of proportion and of incommensurables is one of the most beautiful parts of that exact philosophy which the conventional schoolmasters are constantly seeking to degrade. The old philosophers thought that only a very few men of the most acute race that ever lived on this earth were fit to begin the study of geometry, and we use it as "an instrument for the cultivation of the mind" of the average young barbarian. Even my sense of the parlous state of the country cannot prevent me from grinning at the Rabelaisian humour of the position. Boys are not swine, but if you will force pearls upon them for food (poor boys, they do not know that the pearls are only cheap imitations) you must expect but small results either physically or spiritually. It must always be a pleasant memory to them, however, that they once did have pearls to trample under foot or to give them indigestion, and one may say that they are fairly safe from pearl hunger all the rest of their lives. Will any of my opponents deny that they ceased to study Euclid when they left school, except in the way of their trade as teachers? How many of them know anything of—I need not say Euclid's real philosophy—but even of modern geometry and the beautiful system of transversals developed by the Irish geometers? I recollect a lovely year of my life in which I was introduced to three new things—Tennyson's "Idyls" and McDowell's "Geometry" and Homer's "Odyssey" (Bohn's translation), and I hardly know even now which of the three gave me most pleasure. But I had had the good fortune not to have pearls forced upon me as a boy. Yes, Cæsar wrote a book for the third form; what man who ever passed through the third form would now read Cæsar? Euclid wrote a book for the lower school; a lower school book let it remain.

And $(a+b)^2=a^2+2ab+b^2$ is equivalent to II. 4. And if $\frac{a}{b}=\frac{c}{d}$, then $\frac{ma\pm nb}{pa\pm qb}=\frac{mc\pm nd}{pc\pm qd}$, and this is equivalent to the immortal philosophy of the fifth book. "Great God, I'd rather be a pagan cradled in a creed outworn!" I would rather be utterly ignorant of all the wonderful literature and science of the last twenty-four centuries, even of the wonderful achievements of the last fifty years, than not to have the sense that our whole system of so-called education is as degrading to literature and philosophy as it is to English boys and men.

We are not the heirs of all the ages, and we shall not for very long remain in the foremost files of our time if we depend upon the schoolmasters. I place my faith in the common sense of the common people. In one way or another I find that they are learning to compute, to gain a knowledge of natural science. I know of many hundreds of night-school boys who were poor who are now successful engineers, and already youths are being warned from trying to become engineers because their public school education would actually prevent their having a chance of success. They cannot understand the most elementary lectures in applied science. I know of a large employer who has already told the headmaster of a great public school that he will no longer employ public school boys unless a more rational method of teaching mathematics is adopted. And he is a public school boy himself! I am constantly being asked to recommend men to teach mathematics in technical schools and colleges, and warned that I must not recommend a Cambridge man. There is nobody who has a higher respect for Cambridge mathematics, for the achievements of past and present Cambridge men, than I have; but if Cambridge men will put themselves altogether out of sympathy with the needs of young engineers; if they will make no attempt whatsoever to look at things from the new point of view to which we have been forced; if without any attempt at examination they will in an off-hand way settle it that what we ask for is an illogical and soul-debasing non-educational preparation of an olla podrida of mere formulæ, then in sorrow and not without some anger we must try to get on without them. They do not know what a lovely bit of fighting they are leaving us to do all by ourselves, but I sincerely hope that they will not hamper us. Indeed, they must sooner or later help us against the common enemy, even if they are only to be armed as were the children of the mist. Because Isaac Newton was such a superb bowman and the English yew was ever the finest of materials, they will insist on the use of the antiquated weapon only. I sincerely hope that the English yew, which is very much of a graveyard tree, may not yet flourish over the grave of British industry.

But enough of these notions. I see a great fight ahead of our people, and bows and arrows are better than no weapons, as a twentieth of a loaf is better than no bread at all, and I welcome any instalment of reform, however small, in the teaching of mathematics in the public schools of England. And so long as my help is not rejected on the ground that I openly ask for a much greater reform and may be dangerous to my friends on that account, so long am I anxious to give my help and proud that it should be accepted.

JOHN PERRY.

Birds attacking Butterflies and Moths.

WITH reference to my previous letter in NATURE (January 16), I would say that the butterfly referred to was the *Terias silhetana* or *Terias laeta*, probably both.

Another bird that frequently catches these butterflies on the wing is the Indian Bee Eater (*Merops viridis*).

During a Christmas camp this season I came across a field where some twenty or thirty King Crows were busily engaged in catching butterflies; the day I first saw them, butterflies were numerous in this field, and it was easy to get undamaged specimens of *Terias silhetana*, *Terias laeta*, *Junonia lemonias*, *Tarucus theophrastus*, *Lampides elpis*, *Catopsilia pyranthe*, and some others which were not being caught in flight. Some three or four days later few King Crows were to be seen, the butterflies were much diminished in number, and nearly all those caught were damaged specimens. The birds perched on the tall dry Jowari stalks and made short flights on all sides, catching their prey sometimes on the wing, sometimes on the ground.

I could not say with certainty what butterflies were caught on the wing.

The King Crow and the Bee Eater are two of the commonest birds in this part of the country, and must cause a good deal of destruction in the course of a year.

India, February 21.

"Nature-Study" Exhibition.

WILL you kindly permit me, while thanking you for the attention which you have already directed towards the above exhibition, to state that it has now been arranged to hold it at

the gardens of the Royal Botanic Society, Regent's Park, on July 23 and following days? It will be open to colleges and schools of every grade, and the exhibits will include all that bears upon Nature-study. Happily the project has secured very influential support, and has aroused considerable interest.

Sir John Cockburn, K.C.M.G., is chairman of the executive committee, and Mr. Charles Savile Roundell, of 7 Sussex Square, Brighton, is hon. treasurer.

I shall be happy to furnish full particulars, or to meet anyone, who may wish to see me personally, at any time by appointment either at the Botanic Gardens or in St. James's Street, S.W.

JOHN C. MEDD
(Hon. Sec. *pro tem.*).

Stratton, near Cirencester, March 19.

Sounds associated with Low Temperatures.

THE accompanying extract from a letter recently received from Norwich raises a question that I cannot answer. I have never experienced the fact named. Have any of your correspondents ever done so?

W. H. PREECE.

"On February 18 the temperature went down to zero here. As my son walked about the sheds, he was struck by the whistling noise the ground made, which he says he has noticed each time such an extremely low temperature has occurred, and he reminded me how we had once noticed it together a great many years ago. Now what makes that whistling, and does it always accompany a zero frost?"

Proofs of Euclid I. 5.

I REGRET that in my letter of March 13 (p. 439, line 4) the letters A, B were inadvertently used by me instead of B, C.

I have tried Mr. Croome-Smith's proof (NATURE, March 20, p. 466) on a class of beginners, but it is difficult to convince them that, in the words of the professional conjurer, "there is no deception."

A non-mathematical friend has just written, pointing out that so long as we define a square as a four-sided figure having all its sides equal and all its angles right angles, it is somewhat inconsistent to trouble the beginner with proving properties of an isosceles triangle the truth of which he can readily see for himself at a glance. Either we should make him prove the properties of a square or we might just as well define an isosceles triangle as a triangle having two sides equal, and the angles opposite these sides equal.

G. H. BRYAN.

THE NATIONAL PHYSICAL LABORATORY.

THE Prince of Wales, who was accompanied by the Princess, formally opened the National Physical Laboratory on March 19, in the presence of a distinguished company of men of science and others interested in national progress. In declaring the laboratory open, His Royal Highness said:—

I am glad that my first duty as a Fellow of the Royal Society should be to join with my distinguished brethren in opening this institution, the direction and administration of which have been entrusted to the Society by the Government. It is also a great pleasure to assist in the inauguration of what may fairly be called a new departure, for I believe that in the National Physical Laboratory we have almost the first instance of the State taking part in scientific research. The object of the scheme is, I understand, to bring scientific knowledge to bear practically upon our everyday industrial and commercial life, to break down the barrier between theory and practice, to effect a union between science and commerce. This afternoon's ceremony is not merely a meeting of the representatives of an ancient and world-renowned scientific society for the purpose of taking over a new theatre of investigation and research. Is it not more than this? Does it not show in a very practical way that the nation is beginning to recognise that if her commercial supremacy is to be maintained greater facilities must be given for furthering the application of science to commerce and manufacture? In the profession to which I am proud to belong there are, perhaps, special opportunities of gaining a certain insight into the general trade and commerce of the world and of comparing the commercial vitality of the different countries. And certainly abroad one finds an existing impression, which was confirmed by the experience of my recent and interesting colonial tour, that the superior technical and scientific knowledge of our foreign competitors is one reason why our hitherto preeminent position in manufactures and commerce is so considerably threatened. As a simple example I may quote the opinion of an expert authority in Australia, that the aniline dyes of Germany had given to a certain class of German-made goods a decided superiority over those of British manufacture. In Germany and America much valuable work has been carried out by the State. In this country the Government have provided these buildings and found machinery for the supply of light, heat and power. They are at present not inclined to spend more money upon equipping the laboratories. It is therefore to the liberality of the public that we must look, not only for money, but for presents in machinery and necessary appliances. Already the institution has benefited in the latter respect by gifts from Sir Andrew Noble, the Drapers' Company, Messrs. Willans and Robinson, Lady Galton, and others. The old-established Kew Observatory now forms part of the laboratory. Important and growing work is carried out in the testing of telescopes, binoculars, sextants and, more particularly, telescopic sights for the Navy. Most of the scientific outfit supplied for the Antarctic expedition was tested at Kew. The laboratory will also supply a want which is much felt for standardising and testing the many other forms of apparatus in daily use, while investigations will be carried out on points of importance to the manufacturer or the merchant from the solution of which valuable results may be expected to accrue. I am particularly pleased to know that it is possible that within the precincts of this laboratory there will be established a work of the utmost importance—namely, a tank after the design of the late Mr. Froude, in which the performance of a ship can be predicted from experiments on a model. At present there is such a tank at Haslar, which is fully occupied in Government work. The Institution of Naval Architects, impressed with the demand for this work, have proposed to raise the sum required to erect the tank and for the necessary appliances. But the funds at present at the disposal of the laboratory will require to be considerably supplemented if they are to undertake this much-needed work. No doubt the working expenses of the tank will ultimately be met by fees. But a difficulty may arise in tiding over the interval which must elapse before such fees are available. I am confident that, through the generosity of the public, the necessary means will be forthcoming to meet these difficulties and to secure that which is almost an essential to the shipbuilding industry of a country possessing the largest mercantile marine in the world. Before such an audience I have not presumed to speak of the value to science of this institution. Though the Navy has given many notable names to scientific theory, it is the practical results which naturally appeal more to the mind of the sailor, and I am sure you will accept this as my excuse for having ventured to make my few remarks upon the future of this institution from merely a utilitarian point of view.

At the close of the ceremony, in responding to the vote of thanks, the Prince of Wales announced that Sir William Armstrong, Whitworth and Co. had promised to subscribe 1000*l*. towards the funds of the laboratory; and he expressed the hope, which all of us share, that this excellent example will be promptly followed by other manufacturing firms. We give below some particulars of the work already instituted at the laboratory.

The opening ceremony took place in the engineering laboratory, in which about 900 guests were accommodated. This had been cleared for the occasion, and the only machines left in position were a shaping machine by Baker and Co., of Halifax, and a ten-ton testing machine. The latter is one of Messrs. Buckton's vertical machines. The stress is applied direct by means of a hydraulic ram worked off the main, in which there is about 100 feet of water pressure, so that no intensifier is necessary; the supply from a small cistern fixed to the wall is sufficient to bring the ram back when the pressure is relieved. The machine is intended primarily for experimental work in connection with the alloys research; for this it has conveniences which a more powerful instrument

would not possess, while at the same time it may be useful in making accurate tests on small specimens; such tests the committee is prepared to undertake, though it fully recognises the desirability of erecting a large machine as soon as funds will permit. The usual accessories for torsion and bending tests are fitted; there is also a simple autographic gear.

The pressure pumps for the gauge-testing work supplied by Messrs. Schaffer and Budenberg were placed temporarily in an adjoining room. These are two in number; one is arranged to test simultaneously ten or twelve gauges up to a pressure of 600 lbs. to the square inch; the pressure is applied by a force pump and a screw plunger. In the other, a pressure of twelve tons to the square inch can be obtained easily. The indicator-testing apparatus given by Messrs. Willans and Robinson has not yet arrived. In the engine-room the 75 kilowatt Parsons' turbine was running, and proved an attraction to many visitors. The normal voltage of this machine is about 105. The room also contains a 10 kilowatt dynamo by Thomas Parker and Co., driven by a Crossley gas-engine and a motor generator set also by Parkers. By means of regulating resistances, the dynamo of this set can be made to run at voltages between 10 and 60. There are three storage batteries, each of about 55 chloride cells, in the Laboratory, and by running the generator in series with the main dynamo each of these can be charged. But in experimental work the cells are likely to be unequally used; the generator alone can then be used to charge groups of cells which require special treatment.

With regard to the physical part of the Laboratory, it must be remembered that the staff has only been in the building for a very short period, the electrical rooms were not ready for occupation until about ten days before the opening, and, further, that the funds at the disposal of the committee have sufficed to purchase only a limited equipment. The aim of the director has been to complete as far as possible the apparatus required for experiments which it is hoped to undertake at once; no apparatus has been bought without an express and immediate object in view. The thermometric department is perhaps the most completely fitted. The main laboratory has been divided into two by a partition of soft brick and glass. On the one side are the various furnaces and heating appliances, on the other the measuring instruments which it is desired to keep at a uniform temperature or to protect from fumes. The brick can easily be drilled to allow the passage of wires, tubes, &c.; through the glass the observer can see what is happening on the other side of the partition. Appliances were shown for standardising thermometric instruments from the temperature of liquid air up to 1000° C. or 1200° C. This laboratory is in the charge of Dr. Harker, who has shown much ability in arranging the various appliances.

For the liquid air there is a Hampson liquefier attached to a Brotherhood compressor, which is driven by a 5 h.p. motor by Laurence Scott and Co., of Norwich. For boiling-point observations and for calibration, the standard apparatus as used at Sèvres has been fitted. For temperatures between boiling point and 200° C. to 250° C. an oil bath has been constructed. This consists of a wide U-tube of copper having a junction across the upper part of the U. In the one limb is a stirrer driven by a small motor, in the other the thermometers are placed; thus a continuous stream of oil is driven rapidly past the thermometers. The whole is jacketed and heated by gas, and careful observations have shown that the temperature over the whole of the vertical column is remarkably uniform.

For temperatures up to about 600° C. there is a similar bath of iron containing a mixture in equal parts of the nitrates of potassium and sodium.

The higher temperatures up to nearly 1200° C. are obtained in an electric oven similar to that used by Messrs. Holborn and Day at the Reichsanstalt, and the director is indebted to President Kohlrausch for kind assistance in procuring the materials for this. The oven, which was the gift of Sir Andrew Noble, consists of a series of tubes of porcelain and fireclay carefully lagged with asbestos; round the innermost tube a nickel wire is coiled; this is heated by a current, and a remarkably steady and uniform condition of temperature is obtained; the regulation of the temperature is easy, and there are no fumes to contend with.

For success with the oven it is necessary that the electric supply should be uniform; a special battery of 56 cells has therefore been installed. This has been arranged in four groups of 14 cells each, and by means of a specially devised switchboard these can be combined in various ways to give the required current and voltage. This battery was the gift of Sir Andrew Noble, to whom also is due the gas thermometer which at present forms the standard of reference. For secondary standards, mercury thermometers will be used up to 250° or possibly rather higher; above this platinum thermometers, or possibly thermopiles, will be adopted. Among the exhibits were three thermal-junctions most carefully standardised by Prof. Holborn, which will form a link between the Laboratory and the Reichsanstalt; there was also a platinum thermometer in a quartz tube, very kindly given by Mr. W. A. Shenstone. A cathetometer set up temporarily against the wall attracted special notice.

At no great distance from the thermometric laboratory is the mercury pressure gauge. A glass column some fifty feet high has been fixed to the wall of the laboratory; alongside this is a steel scale, divided into millimetres, pounds per square inch, kilogrammes per square centimetre, and feet of water; thus gauges up to a pressure of 250 lbs. to the inch can be tested directly against the column. A lift erected close to the column enables the observer to read the height of the mercury. The pressure is applied by means of compressed air contained in a bottle connected both to the gauge and the mercury column. The bottle will be filled from the Brotherhood compressor which works the air liquefier. For standardising gauges between 250 and 400 lbs. pressure, a loaded piston apparatus—a gift from Messrs. Willans and Robinson—will be available; for pressures above this, apparatus has to be constructed.

The metallurgical department is housed in the old kitchen, in which there was an interesting exhibition of photographs of metallic sections and cooling curves, lent by Sir William Roberts-Austen. The apparatus for investigating cooling curves has yet to be bought, but a beautiful photomicrographical outfit by Zeiss was shown by Dr. Carpenter, who exhibited to a number of the guests the section of a steel rail magnified four hundred times; the pearlite and ferrite structures were clearly visible; the rail had been rolled cold and the grains were elongated by the rolling. The projection apparatus is very complete; the arrangements for cutting, grinding and polishing the sections are also ready; the polishing apparatus has been specially designed by Mr. J. E. Stead, and the laboratory is prepared to undertake the microscopic examination of sections for the railway companies or other users.

A room adjoining the microscope is arranged for metrology, and here were set up a dividing engine by the Société Génevoise pour la Construction d'Instruments de Physique. This instrument was given by Sir Andrew Noble, and is a copy of that in use at the Bureau International, but without the automatic mechanism—this, however, can be added if funds permit. It will divide lengths of 1 metre or less. The room also contained a Whitworth measuring machine, a set of standard gauges, surface plates, &c. A set of screw gauges had most kindly been lent by

Messrs. Sir W. G. Armstrong, Whitworth and Co., who exhibited in addition Sir J. Whitworth's original measuring machine. A Pratt and Whitney measuring machine has not yet arrived. In an adjoining room, thanks to the courtesy of Sir F. J. S. Hopwood and Mr. Chaney, there was an interesting exhibit from the Standards Department of the Board of Trade. King Henry VII.'s yard and Queen Elizabeth's pints were shown in proximity to our modern standards.

The electrical rooms are three in number. One of these, in the basement, has a constant-temperature chamber attached, and here were the British Association standards of resistance; the coil "Flat" made by Matthiessen about 1864 and used by the original British Association Committee on Electrical Standards was shown to visitors, as well as some modern standards.

The main electrical laboratories, however, are far from complete; one of these, which is to be used for the fundamental units and standards, was occupied as a tea-room. In the other, Mr. Campbell had, in the ten days which had been available, set up some secondary standards in their permanent positions, while other apparatus was exhibited on tables in the middle of the room. A few antiquated scales of historical interest aroused some criticism. They were merely placed on the tables with the other apparatus to indicate that a galvanometer with some proper arrangement of lamp and scale formed part of the installation required.

The fundamental standard of electromotive force will be the Clark cell, while current will be measured by the drop in volts over a known resistance; but for secondary standards a Kelvin multicellular voltmeter of somewhat special construction, a set of Kelvin balances and some Weston instruments will be employed. The voltmeter is read on a long scale in the form of the arc of a circle some two metres in radius. Between 60 and 110 or 120 volts the scale is a very open one, some 5 cm. corresponding to one volt. Thus it is easy to read to the tenth of a volt. For use with the instrument a special resistance box containing ten coils has been wound by Mr. Campbell.

The first coil of 10,000 ohms resistance is divided into two parts. One of these has a resistance of 1500, the other of 8500 ohms; each of the others is 10,000 ohms. Each coil is of manganin, wound in sections, which are arranged so as to be non-inductive, and each coil will stand an E.M.F. of more than 100 volts. Thus 1000 volts may safely be applied to the whole. A current can be passed through the whole box and adjusted by means of external resistances until the drop between the first and second terminal just balances the E.M.F. of one Clark cell—14,340 volts—in series. In this case the drop across each coil after the first is 10 volts, and by connecting the voltmeter in turn to the proper terminals of the box its scale can be calibrated. When this has been done the instrument is ready for reading directly potential differences between 50 and 120 volts; below 50 the scale is too contracted. To measure voltages above 120 volts, the box is used; the total volts are put on between the end terminals; the box enables these to be subdivided to tenths, and a convenient number of tenths can be measured directly on the voltmeter scale.

In another corner of the room were the standard air condensers of the British Association; these, which consist of a series of concentric cylinders, have been described by Mr. Glazebrook in some of the reports of the Electrical Standards Committee; on a table near by was shown the apparatus for determining their capacity, a Wheatstone's bridge box of platinum silver coils by Elliott Bros. and a rotating commutator made by Pye and Son, of Cambridge, the speed of which is controlled by a stroboscopic arrangement viewed through diaphragms attached to a standard fork.

It is intended at once to set about constructing from these condensers standards of capacity for commercial use.

On another table was set up in a convenient form the apparatus for measuring by the ballistic method the permeability and hysteresis of an iron ring, while close by the latest pattern of Ewing's permeameter was on exhibition.

In the centre of the room were shown two resistance boxes by Wolff, of Berlin; one of these was a potentiometer box with a wide range of applicability, the other an ingenious modification of the Kelvin double bridge which is used extensively at the Reichsanstalt for the measurement of small resistances.

The commercial testing of iron and steel or of measuring apparatus, if undertaken on a large scale, will probably be carried out ultimately in a room attached to the engineering laboratory; most of the arrangements which have just been described are fitted rather for the construction and verification of secondary standards than for purely commercial testing.

A fourth wing of the building contains the chemical laboratory, which calls perhaps for no particular description; it was described as workmanlike by a very capable judge on the nineteenth, and that may suffice. A chemical laboratory is essential, but it is not desirable that it should be very elaborate.

The laboratory contained a large collection of glass vessels, flasks, burettes, &c., lent by Messrs. Gallenkamp; these were intended to illustrate one branch of the new work, the standardisation of such apparatus for which there seems a great opening. The vessels exhibited bore the stamp of the Reichsanstalt.

The system of electric wiring adopted requires a special notice. There are two distinct sets of circuits; one of these, connected to the lamps and to numerous plug points, is fed from the dynamo or the cells at a steady voltage of 100 volts. It is used for lighting and for the supply of power.

For the experimental work there is a separate battery of 55 cells. These are arranged in groups of 5, the first group being further subdivided; the positive poles of the cells are connected to a series of horizontal brass bars at the back of the main switchboard; the negative poles are connected to a series of isolated blocks, which, by means of switches on the front of the board, can be put into contact with the corresponding horizontal bars; the positive pole of each group is one bar lower than the negative pole of the same group. Thus if the switches are all closed the cells are in series; the top horizontal bar is negative, and there is a constant rise of 10 volts between each two consecutive bars. On the front of the board are a series of vertical bars, and from the tops of these the experimental circuits, of which there are thirty, lead away through fuses. These vertical bars can be plugged through to the horizontal bars at the back, and thus a series of voltages rising by steps of 10 volts can be distributed through the building.

The normal discharge rate of the cells is 50 amperes, but to obtain higher rates the cells can be connected in groups of five in parallel. To do this with all the groups, all the switches are opened; two specially heavy vertical bars are then connected by plugs, the one to all the positive poles, the other to all the negative poles of the battery. From these bars two circuits capable of taking 500 amperes lead away.

The switchboard, which is a modification of that at the Owens College Laboratory, was designed by Mr. G. A. Steinthal, of Bradford, in accordance with the suggestions of the director. Mr. Steinthal has carried out all the experimental wiring. The distributing wires are for the most part bare copper, and are carried on porcelain insulators. Some of these wires go directly to the various rooms, and are so arranged that it is possible in any room to obtain simultaneously at least two different voltages. Others of the distributing wires go to three subboards arranged in a similar manner to the main board; four circuits from the main

board go to each subboard, and twelve subsidiary circuits leave it. In the main electrical laboratories there are five of these subcircuits, and to avoid magnetic action concentric wiring has been used in the section. Each board is fitted with a voltmeter, so that the voltage can be tested before connection is made with any instruments. Thus the electrical equipment, so far as it goes, is unusually complete. It should be noted, however, that provision is still required for alternating current supply and for voltages above 110 volts. Arrangements have been made by which the experimental battery can be put on to the lighting circuit, or run in series with the lighting battery to get 220 volts, but it is not anticipated that this will often be done. As soon as funds permit, the outfit will need supplementing in this respect.

It will appear from the above that there is much to be done before the Laboratory can be called complete; still, for many branches of its work it has the means to start, and its success in these will lead to increased opportunities for development.

THE SCENERY OF ENGLAND.[1]

IT is curious to reflect on the history of man's inquiry into the origin of the landscapes among which he has lived for so many thousand years, and to find how recent is his intelligent interest in the subject. Within the memory of many who are still alive and active, the present topography of the land hardly came within the scope of scientific investigation, and while the utmost energy and enthusiasm were displayed in unravelling the secrets of the rocks below the surface and thus reconstructing the geography and scenery of the successive eras of the geological past, only meagre attention was given to the causes which had brought about the existing features of that surface. The popular notion that everything remained as it had been from the beginning was known to be untenable and absurd; nevertheless, the subject failed to excite the interest of geologists as a body. Some of them were Wernerian tories, others Plutonist conservatives or Uniformitarian liberals; but whatever might be their geological creed, they were for the most part Gallios in this matter, never caring to set themselves seriously to consider how their familiar hills and valleys were in detail to be accounted for.

Yet the way had been shown to them generations before. It had been opened up by Lazzaro Moro and Generelli in Italy; by Ray and afterwards by Hutton and Playfair in this country; and by Guettard and Desmarest in France. Living on an island and accustomed to continual tales of the destruction wrought by the sea on the margin of the land, British geologists, largely influenced in later years by Lyell, had come to look upon the sea as the prime agent in the degradation of the terrestrial surface. They had no theoretical objection to depressing or uplifting the land to any extent that might be desired, in order to account by marine erosion for any particular topographical feature. While admitting the existence of what were called "valleys of denudation," they thought it much more probable that these hollows had been scooped out by violent inundations of the sea, or by ocean currents moving with great velocity over the submerged country, than that they could have been carved out by such seemingly feeble agents as the rivers that flow in them. The admirable demonstration given by Desmarest, as far

FIG. 1.—Granite Coast, Cornwall.

[1] "The Scenery of England and the Causes to which it is Due." By the Right Hon. Lord Avebury. Pp. xxvi + 534. (London: Macmillan and Co., Ltd.) Price 15s. net.

back as 1774, that a system of valleys, like that of Auvergne, had been carved out by running water in a series of rocks of varying powers of resistance, including even thick and wide sheets of solid lava, failed to impress the geological mind. The subsequent enforcement of the same lesson from the same region by Poulett Scrope in 1826, and three years afterwards by Lyell and Murchison, likewise roused no general interest. English geologists, while they admitted that such a process of land-sculpture might very well be allowed to have been effective in the heart of a foreign country, far from the sea and high above its level, remained true to their impression that, by invoking convulsions of the solid ground below and sufficiently destructive operations of the sea above, they could satisfactorily explain all that seemed to need explanation in the topography of the land. How deeply rooted this prejudice was is well shown in the memorable paper by Ramsay on the denudation of South Wales and the adjacent English counties, published in 1846. This great classic holds, and deserves to hold, an honoured place in geological literature, as the first concrete attempt to work out in some detail the denudation of a region with reference to its geological structure. Yet at that time, being as marine as the staunchest adherent of the old faith could desire, its author scouted the idea that rivers and streamlets had played any notable part in carving out the valleys of the country. With the naïve remark that "it is not to be expected that an unaccustomed eye should at first detect all the evidences of the former action of the sea on these lands," he affirmed that "we must either adopt the theory that the great features of the land have resulted from the ordinary action of the sea, or else revert to the hypothesis of great bodies of water violently rushing over the surface." These views continued to prevail for twenty years longer. Their last champion was probably the late Dr. D. Mackintosh, whose "Scenery of England and Wales" appeared in 1869.

But some years before that date the first step in the application of Hutton's teaching to the history of the valleys of this country had been taken by Beete Jukes, who broke new ground and opened the eyes of his brother geologists to the true nature of the problems of topography by the publication of his ever-memorable essay, "On the Mode of Formation of River Valleys in the South of Ireland," which was issued in 1862. The examples cited this time were not from a foreign country, but from our own islands, where they could be judged of and criticised in the light of all that was known of a similar nature in other parts of Britain. The process of time had fitted the soil of the geological mind for the seed, and it soon sprang up and bore fruit. Next year (1863) Ramsay showed in the first edition of his "Physical Geography and Geology of Great Britain" that his old faith was weakened, and that he was prepared to follow his friend and colleague in what was really a return to the Huttonian fold. At that time the Geological Survey was at work on the Weald under Ramsay's supervision, and had to face the problem of its denudation, which had been so often described and discussed and had so complacently been assumed to be a proof of the levelling action of the sea. For the first time in England a tract of country which was geologically mapped in detail was simultaneously subjected to a searching inquiry as to the history of its topographical features. The officers of the staff, after an exhaustive examination of the ground, were led to discard the doctrine of marine erosion and to adopt in its stead that of long-continued subaërial waste. They showed convincingly how this explanation reconciled all parts of the evidence, and how each new

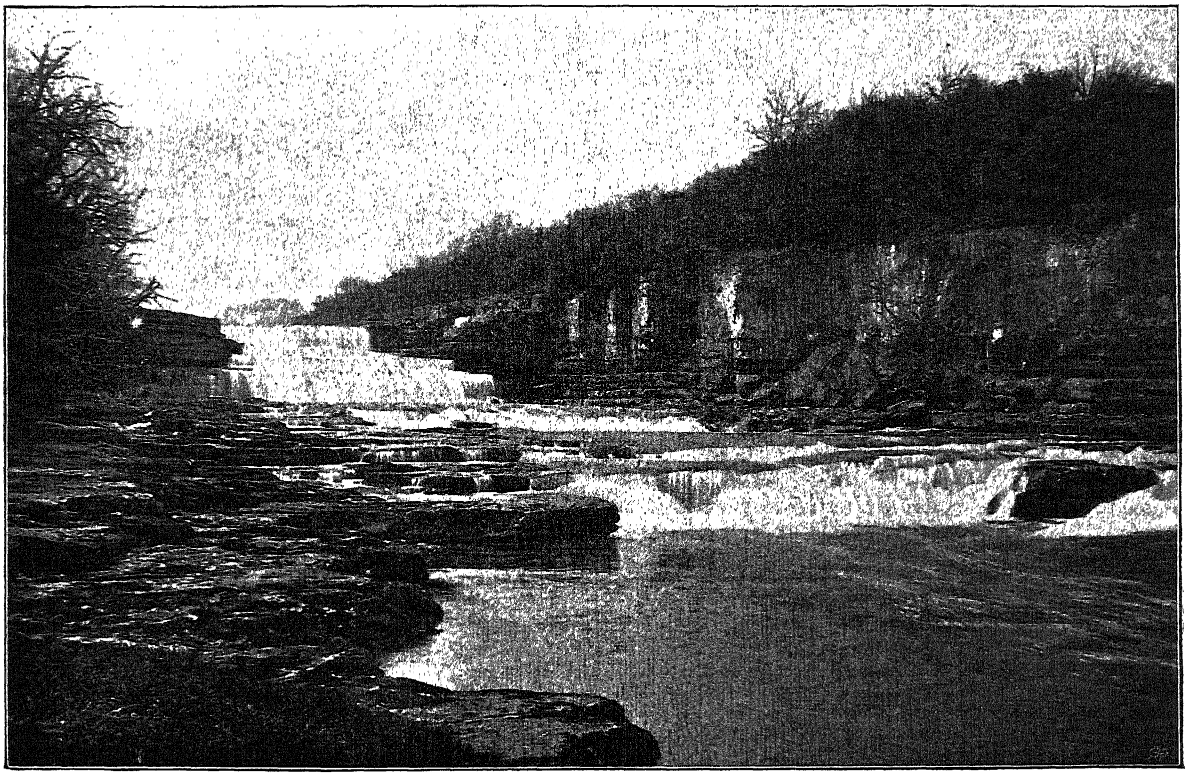

Fig. 2.—Lower Fall, Aysgarth, Wensleydale, Yorkshire.

observation advanced and confirmed the deduction that the valleys which diverge from the Weald began to be eroded by the streams that flow in them when the drainage descended from the still existing dome of chalk, and that during the enormous time in which atmospheric degradation has been at work that dome has been completely removed, the rivers gradually sinking to lower levels, but still continuing to flow outward as at first. Ramsay proclaimed his conversion to these views in the second edition of his book, which was issued in 1864. Next year there appeared the detailed essay on the subject by Dr. C. Le Neve Foster and the late Mr. Topley, which established beyond all further doubt the potency of atmospheric decay and river-erosion in the sculpture of the surface of this country.

The Huttonian doctrine, though thus long in gaining acceptance, made rapid progress when once a few enthusiastic workers, drawn under the spell of its attractiveness, began to apply it to the interpretation of all parts of the British Isles. In England and Wales, in Scotland and in Ireland, it gained every year an increasing number of followers, many of whom, with the usual geological alacrity, have contrived to pile up quite a respectable mass of scientific literature devoted to its discussion and promulgation. This great phalanx of observers and writers on the subject has now to hail as its latest recruit Lord Avebury, who has given another proof of his versatility by a contribution of more than 500 pages to a discussion of the origin of the scenery of England and Wales. Encouraged by the favourable reception accorded to his volume on the "Scenery of Switzerland," he has been led to produce another on that of his own country. Paradoxical as it may seem, it is nevertheless true that the task he set before himself in the preparation of this work was in many respects more difficult than that of the earlier publication. Notwithstanding the complicated structure of the Alps, the story of the origin of their valleys and the sculpture of their great blocks of mountain is on the whole less complicated and obscure than that of the tamer English landscapes. In this country the problems of topography involve questions of higher antiquity and lead the inquiry into a domain where the evidence is less distinct and abundant, and where a larger demand is made for detailed knowledge of the geological structure and history of the ground.

Lord Avebury devotes his earlier chapters to an outline of the geology of the country, and gives a brief account of the various rocks from the oldest to the youngest. In dealing with the scenery, he begins at the coast-line and notes the distinctive characters of our shores with the causes to which their variations are due. With regard to the interior, after some general statements respecting the movements of the terrestrial crust and their effects, he discusses the distribution, structure and origin of the mountains and hills, citing numerous examples from different parts of the country. He then passes on to the consideration of the rivers, dealing first with the general history of a typical river and illustrating his subject by references to the various English and Welsh streams by which the successive features of that history are best displayed. From moving water he naturally turns to the lakes, and picks his way with great skill among the rocks and shoals of that much-debated subject. The influence of the rocks in determining variations in the character of the landscapes is rapidly treated in a single short chapter, which is followed by one that probably gave him as much pleasure to write as any part of the book, for it deals with the downs, wolds, moors and commons which have been so familiar and delightful to him all his life. The next two chapters are not unlikely to have more interest for the unscientific reader than the rest of the volume, seeing that they treat of the connection of certain topographical features with old systems of land-tenure and methods of agriculture. They show why parish-boundaries run as they do and what causes have often determined the sites of towns. We are led across the country from one interesting historical spot to another, and are finally brought back to London and set to think of the geological reasons that have fixed the position of the chief city of the empire. It might, perhaps, have been better had the book appropriately ended there, but a final chapter is added in which, quitting the scenery and history of the Thames valley, the reader is suddenly plunged into the "nebular theory" and the tetrahedral collapse of the globe.

In his preface the author expresses a hope that the book may prove half as interesting to read as he has found it to write. Every reader must recognise the enthusiasm with which Lord Avebury has followed out his self-imposed task in a field which he had not made specially his own. He has brought together in readable compass a summary of what has been done in the investigation of the history of the scenery of England. Every here and there his narrative glows with the fervour of a true naturalist, as where he describes the shore-life of our coast-line with a minuteness which shows how closely he has observed, and with a breadth that brings the whole scene before us, or where he depicts the charms of the downs, noting their wild flowers one by one, and carrying us with him over their breezy crests, past green barrow and grey standing-stones. His book will doubtless do good service in attracting more general interest to one of the most fascinating branches of geology.

One feature of the volume gives it a special attraction. It is profusely provided with illustrations from photographs of English scenery, chiefly selected from the great collection which is gradually being gathered together by a committee of the British Association. We give two of them in this article, by way of examples (Figs. 1 and 2). Most of them have never before been published. But, beside the charm of novelty, they possess the still greater merit of having been taken, either by geologists or others, for the express purpose of preserving a record of interesting geological features. Those chosen for this volume have been excellently reproduced, and the printing of them is perhaps as near perfection as can be secured for illustrations that are printed with the general body of the type. The name of Messrs. Clark is a sufficient voucher for the beauty of the typography. But how did their reader or pressman allow the map (Fig. 183) to appear upside down?

Lord Avebury has not adopted the topographical nomenclature which our cousins on the other side of the Atlantic have devised and seem to be so proud of. Like other writers in this country, he has been able to treat his subject in plain English words, without recourse to a set of uncouth terms which are as unnecessary as they are undesirable.

The history of the landscapes of England, notwithstanding all that has been published on the subject, still presents many difficult problems for solution. Though Ramsay in his later papers so ably led the way, one great cause of stumbling to many of the workers in this field of inquiry still arises from their inability to realise the vastness of the denudation of the country within Tertiary and recent times. They shrink from the boldness of covering hundreds and thousands of square miles of ground with formations of considerable thickness, every vestige of which has disappeared. Yet it is only by conceding the former existence of such formations that they can possibly explain the present topography of the country and lines of drainage. The mere existence of an area of Palæozoic formations at the surface, especially, too, where it forms high land, ought to be regarded as in itself a proof that, for a vast period of time and until a comparatively late date, that area must have lain under a covering of later rocks. It was over this vanished,

covering that the present drainage system began to be traced, and the channels originally chosen by the streams that first flowed over it still, on the whole, keep to the same courses, though they have now cut their way down into the older rocks. The most helpful line of investigation that can at present be pursued in this subject is to be found in the search for actual or probable evidence of the extent of the denuded formations. The recent discovery by the Geological Survey of masses of Rhætic, Liassic and Chalk strata in a Tertiary volcanic vent in the Isle of Arran, which proves the former extension of these formations into the west of Scotland, is an example of the unexpected way in which the most important evidence may at any moment be discovered. But even if no such evidence should be forthcoming, it is impossible to contemplate the prodigious denudation of the country even among solid massive rocks like the lavas of the west of Scotland without the profound conviction that since Tertiary time hundreds of feet of rock have been removed from the surface, and that it is impossible to comprehend the history of our landscapes without taking this momentous fact into account.

THE ROYAL SOCIETY AND THE PROPOSED BRITISH ACADEMY.

THE following letter on this subject appeared in the *Times* of March 20 :—

To the Editor of the TIMES.

SIR,—In the references which have been recently made to the early history of the Royal Society, the charters of King Charles II. have frequently been remarked upon, and also the subject-matter of the communications published by the *Philosophical Transactions* from time to time. It has been conceded by many who have given attention to the matter that the charters of King Charles II. intended that the then newly-founded Society should take cognisance, not only of observational and experimental science, but also of those philosophical, historical and philological subjects for which, on the ground that they lack representation to-day, King Edward VII. has been petitioned to grant a charter enabling some new body to look after their interests. It has also been conceded that the early practice of the Royal Society was in accordance with the suggested intention referred to above, so far as the communications made to it enable us to form a judgment.

In a previous letter on this subject, which you were good enough to insert in the *Times* of January 29, I pointed out that a committee specially appointed by the Council of the Royal Society to consider the matter had reported, after consultation with high legal authorities, that the inclusion of the subjects within the scope of the Royal Society, for the general organisation of which it is now proposed to found a new Academy, is within the powers conferred on it by the charters of that Society. I venture to give two extracts from the first charter granted by King Charles II. which alone seem to establish this conclusion. If you will permit me, I will reproduce them here :—

Charles II., by the grace of God King of England, Scotland, France and Ireland, Defender of the Faith, &c., to all to whom these present Letters shall come, greeting.

We have long and fully resolved with Ourself to extend not only the boundaries of the Empire, but also the very arts and sciences. Therefore we look with favour upon all forms of learning, but with particular grace we encourage philosophical studies, especially those which by actual experiment attempt either to shape out a new philosophy or to perfect the old. In order, therefore, that such studies, which have not hitherto been sufficiently brilliant in any part of the world, may shine conspicuously amongst our people, and that at length the whole world of letters may always recognise us not only as the Defender of the Faith, but also as the universal lover and patron of every kind of truth : Know ye, &c.

Of the "Fellows" it is written :—

The more eminently they are distinguished for the study of every kind of learning and good letters, the more ardently they desire to promote the honour, studies and advantage of this Society . . . the more we wish them to be especially deemed fitting and worthy of being admitted into the number of the Fellows of the same Society.

Of course it would have been very much more satisfactory if the committee, instead of enunciating pious and legal opinions as to what the charters enabled the Society to do, as abstractedly as if the Society had never existed, had, seeing that action under the charters had been going on for nearly two centuries and a half, told us what the Society had really done year after year in the matter of choosing men for election into the Society. In this way sure proof could be obtained of the general opinion of what the charters empowered and enjoined the Society to do, not only at the time they were conferred, but at subsequent dates. This course, which obviously is the only satisfactory way of arriving at a conclusion on the questions at issue, was, however, not open to the committee ; for a complete list of the officers, Fellows and foreign members elected in each year from the foundation of the Society was not generally available.

This gap in our knowledge of the actual life of the Society has recently been filled, and we can now learn the kind of work for which the Society considered itself responsible by the men it elected to do it in its early days, and especially by those who were elected to fill the various offices. It will be obvious that a complete inquiry of this nature is a matter involving considerable time and labour ; but in the present state of the question raised by the proposition for a new British Academy it is of such high importance to know the facts that I have not hesitated to try to get at them, however imperfectly ; my inquiry being limited as much as possible, this has been done by passing over all doubtful cases and considering chiefly the first century of the life of the Society, that is from 1663.

The general result of this limited inquiry may be stated as follows :—

I begin with the presidents. Some were appointed on account of their rank, others on account of their contributions to observational or experimental science, among them Wren, Newton, the Earl of Macclesfield, and others. But besides these we have Sir John Hoskins, "a most learned virtuoso as well as a lawyer," according to Evelyn ; Samuel Pepys, of diary fame ; Martin Folkes, an antiquarian, "under whom the meetings were more literary than scientific" ; Sir James Burrow, an antiquarian, also a lawyer ; and James West, another antiquarian and collector of coins, and given to "black letter lore." If we pass the first century, we find Sir John Pringle, a learned physician and professor of metaphysics and moral philosophy, elected in 1772, and Davies Gilbert in 1827, who, although addicted to science, was chiefly an antiquarian and historian.

Among the treasurers we find one of the first appointed Abraham Hill, given as much to moral as to natural philosophy ; Roger Gale, an archæologist and numismatist ; and, again passing the first century, Wm. Marsden (1802), an Oriental scholar, and Samuel Lysons (1810), an antiquarian and an artist.

We next come to the secretaries. The most remarkable thing about these officers is that between 1663 and 1765, of the twenty-nine elected no less than sixteen were doctors of divinity, medicine or law ; and, so far as the inquiry has gone, the "Dictionary of National Biography" shows that they were not merely professional men, but scholars first and writers afterwards. The secretary elected in 1776 was Joseph Planta, the librarian of the British Museum ; while in 1812 Humphry Davy was followed by Taylor Combe, an archæologist and numismatist.

The office of foreign secretary was created in 1723. Of the eight appointed down to 1772, four were doctors of medicine, and they were selected possibly for the same reason as their colleagues among the secretaries. Maty, who was elected in 1772, was the assistant librarian in the British Museum.

The enormously wide area of knowledge from which the officers of the Society were drawn during the first century is in sharp antithesis to the narrow ground of award of the Copley medal, which was first conferred in 1731. The grant of this medal is limited to the author of the most important discovery or contribution to science by experiment or otherwise; and the greater the divergence between the officers' and Copley medallists' lists, the less, naturally, was the limitation of the Fellowship to those interested alone in experiment or observation.

We next come to the Fellows of the Society. The following lists are based upon a rapid reconnaissance of those who occur early in the alphabetical order, using Hole's "Brief Biographical Dictionary" as a means of determining their identity. The names of many Fellows are absent from Hole, and there are some incertitudes, besides which Hole's definitions are very terse. The lists, however, are given for what they are worth; and there can be little doubt that they will soon be replaced by complete and authoritative lists officially compiled. It is important that the Lords of the Privy Council should possess such documents to assist them in the important inquiry with which they are charged; and we may hope that this eagerness to possess is only equalled by the anxiety of the Royal Society to provide them if their compilation be in the interests of truth:—

Although the matter has not as yet been inquired into, there is already ample evidence that the foreign members were selected with the same catholicity as the ordinary Fellows. Thus Sorbière, an eminent French *littérateur*, was elected in 1663 (the first year); the Italian historian Gregorio Leti was elected in 1681; and the French historian Michael Le Vassor in 1701.

It does not seem possible that any unprejudiced mind, after a perusal of the above statements, limited though they are to a point of time, and, in the case of the Fellows, to a few letters of the alphabet, and inaccurate as they may well be here and there, can deny that the reconnaissance affords valuable evidence that the action of the Royal Society for the first century after it had received its charters was as broad as the charters themselves. The Society tried to do, and succeeded in doing, the duty which the charters imposed upon it.

We learn from the above statements that for the period over which my hasty inquiry has gone, Britain possessed a general organisation of learning as complete, though not so detailed, as that of the Institute of France or any other foreign academy to-day. King Charles II. had, in fact, in his charters, and the Royal Society had, in fact, in its action upon them, anticipated the work of Napoleon by very nearly a century and a half; the portals of the Royal Society and of the Institute of France were equally wide, and wide enough to admit the most illustrious men produced in each country.

If I have erred in any way in reading the facts or in drawing conclusions from them, I sincerely trust that someone with more leisure and knowledge than I will discover where I have gone wrong and at once put the matter right. I am the more anxious that this should be done because I gather from the petition of the Royal Society Council to King Edward VII., which was printed in the *Times* of February 27, that the condition of things which the facts reveal is either unknown to the Council or regarded by them as a matter not worth mentioning.

In that petition His Majesty is informed that the President and Council are of opinion that the studies which it has been shown were fully provided for by King Charles II.'s charters to the Royal Society, and "taken care of" for, at all events, the first century to which my inquiry was limited, "ought to be taken care of by some academic organisation, and that this should be effected, not by the Royal Society taking charge of these studies, but by the establishment of some other body."

I submit, Sir, that the view that a complete inquiry should be made before any step be taken towards creating a new body to do what the charters of King Charles II. enjoined and empowered the Royal Society to undertake is vastly strengthened by the facts now brought to light, which show us what the Royal Society actually did.

This inquiry was thus referred to in the petition to the King, dated February 14, which was signed by many eminent representatives of the intellectual, industrial and other forces of the Kingdom:—

> We Your Petitioners humbly pray that Your Majesty may be graciously pleased to cause an inquiry to be made with a view of instituting a general and formal organisation of all the studies depending upon scientific method now carried on similar to that inaugurated for the philosophical studies of the seventeenth century by the charters of His Majesty King Charles II.

I, am, Sir,
Your obedient servant,
NORMAN LOCKYER.

Athenæum Club, March 11.

ANNOUNCEMENT OF NEW MAMMALIAN REMAINS FROM EGYPT.

THE discovery of ancestral Proboscidean and other remarkable mammalian forms in the Egyptian desert has already been noticed in NATURE (vol. lxiv. p. 582). Dr. C. W. Andrews's preliminary descriptions of the remains show that the deposits are of deep interest to palæontologists and other students of mammalian morphology and distribution. Mr. H. J. L. Beadnell now announces, in a pamphlet of two pages of text, illustrated by six plates, that explorations of the desert bounding the

Fayum depression have led to the discovery of several new creatures. "The most important of these," he says,

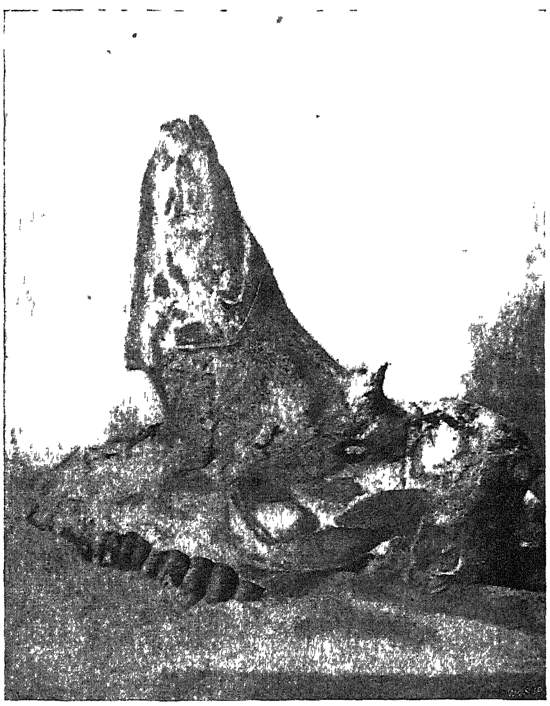

FIG. 1.—*Arsinoitherium Zitteli*, Beadn. Side View.

"is a large, heavily built, ungulate, about the size of a rhinoceros, and for which the writer proposes the generic

FIG. 2.—*Arsinoitherium Zitteli*, Beadn. Back View.

name Arsinoitherium, from Queen Arsinoe, after whom the Fayum was called in Ptolemaic times, the species being *A. Zitteli*, in honour of the eminent geologist, who may be regarded as the pioneer of geology in Egypt, and whose work when attached to the Rohlfs Expedition of 1873-74 is well known to all geologists." The accompanying illustrations, reproduced from the paper, show a side view (Fig. 1) and a back view (Fig. 2) of the type specimen.

BRYAN DONKIN.

BY the death of Mr. Bryan Donkin at Brussels on March 4 the engineering profession has lost one of its members who devoted himself with more than ordinary assiduity to the scientific side of his calling. The name of Bryan Donkin was eminent in the world of mechanical engineering for the whole of the last century. The late Mr. Donkin succeeded, in due course, to the management of the business which his grandfather, the first Bryan Donkin, had founded in 1803 for the manufacture of paper-making machinery; a new process for producing continuous rolls having been then recently introduced. Bryan Donkin, jun., as the subject of our memoir was known until quite recent times, was born in 1835, and was educated at University College, London, and at the École Centrale des Arts et Métiers in Paris, where he was for two years. After that he was apprenticed to his uncle at the Bermondsey works, his father, John Donkin, having died at a comparatively early age. In 1859 he went to St. Petersburg to superintend the erection of a large paper mill which was being established under the Imperial Russian Government for the manufacture of bank notes and State papers. He returned to this country and in 1868 became a partner in the Bermondsey firm. In 1889 the business was turned into a limited company, of which Mr. Donkin was chairman.

It was not, however, as the head of a manufacturing business that Mr. Bryan Donkin was best known in engineering circles, but as an experimenter and a student in thermodynamics and a reader of papers before technical societies. His first important work was undertaken in conjunction with Mr. Farey, who was also a partner in the Bermondsey firm. The latter had invented a steam-engine, which was known by his name, and it was determined that a complete test should be made to ascertain its efficiency. One of these engines had been erected to drive a paper mill in Devonshire, and the method of testing by measuring the heat discharged with the condensing water was adopted. The principles then followed are now well known, but thirty years ago scientific testing was a very rare thing among engine makers. The temperature of the water was naturally not difficult to ascertain, but to measure the volume with accuracy was a formidable task. How this was done by means of the notched weir and the application of a simple hydraulic law is too familiar to all engineers to need describing afresh.

Mr. Donkin carried on an extensive correspondence with continental engineers; probably he was more closely in touch with foreign scientific experts in the field of steam engineering than any of his compatriots. He devoted a great deal of attention to the use of superheated steam, and in the course of some experiments he devised an instrument he designated the "steam revealer." It consisted essentially of a glass vessel into which steam from the engine cylinder was admitted. By observing whether the steam was transparent or was clouded by the presence of watery vapour, it was possible to estimate if the steam were either superheated or saturated, or whether liquefaction had set in. A paper on this subject was read by its inventor before the Institution of Mechanical Engineers in October, 1900. Of late years Mr. Donkin devoted a good deal of attention to internal combustion motors. A book on "The Gas

Engine," which was from his pen, was published by Messrs. Griffin and Co. He also translated Diesel's work, "The Theory and Construction of the Rational Heat Motor." During the whole of his career he was constantly engaged in experiments of various kinds, one of the principal series being the tests he made, in conjunction with Prof. Kennedy, on the steam boiler. In 1898 a work which he had written on the subject was published by Messrs. Griffin and Co.

Mr. Donkin was a member of the Institution of Civil Engineers, from which society he received the Watt medal and Telford and Manby premiums; a vice-president of the Institution of Mechanical Engineers, and a member of various other scientific and technical societies.

NOTES.

M. YERMOLOFF has been elected a correspondant of the Section of Rural Economy of the Paris Academy of Sciences, in succession to the late Sir J. B. Lawes.

IN connection with the survey of British lakes provided for by the Pullar Trust, Sir John Murray has rented Rannoch Lodge, standing at the west end of Loch Rannoch, from now until the commencement of the shooting season. In the first week of April the following gentlemen will join him and will be associated with him in the work, viz., Mr. R. M. Clark, Aberdeen, Mr. T. N. Johnston, Edinburgh, Mr. James Parsons, London, and Mr. James Chumley, Edinburgh. Other appointments will be made later in the season. Sir Robert Menzies, who has taken a great interest in these investigations, and has placed boats, &c., at Sir John Murray's disposal for carrying on the work, has said that all Highland proprietors should render any assistance in their power to the survey by offering the use of boats. It is intended to include within the scope of the survey, in addition to the systematic physical and biological investigations, observations regarding the oscillations in the level of the water (phenomena called "seiches" by Prof. Forel) by means of self-registering "limnographs," which will be set up on the shores of the larger lakes. The first limnograph is now in process of construction in Geneva under the personal supervision of Prof. Ed. Sarasin, of Geneva. It will be remembered that Mr. Laurence Pullar, of Bridge of Allan, has set aside funds to aid in carrying out this survey, as a memorial to his son, the late Mr. Fred. P. Pullar, who was engaged (in collaboration with Sir John Murray) in a systematic survey of the Scottish lakes at the time of his accidental death in February of last year.

MR. J. HUTCHINSON, F.R.S., went to South Africa recently to study the local diffusion of leprosy there. The *Times* announces that he has now returned; and the conclusion to which he has arrived is that the primary cause of the disease is the use as food of badly-cured salt-fish. Whilst believing that this has been by far the chief agent in its diffusion, Mr. Hutchinson thinks he has obtained conclusive evidence that the malady may, in very exceptional circumstances, be communicated from person to person. He does not believe that it is either infectious or contagious in the proper sense of these words, but that it may be communicated by eating food contaminated by a leper's hands. The measures suggested for the prevention of the disease are, first (and by far the most important), the legislative control of the fish-curing establishments; secondly, the diffusion of information as to danger of communication; and thirdly, the establishment of small isolation homes into which lepers should be induced to go during the stage involving risk.

IT is stated that Prof. E. von Behring intends to give the amount of the Nobel prize recently awarded him (8400*l.*) to the Prussian State for the permanent endowment of the Institute of Experimental Therapeutics founded by him in the University of Marburg. The gift is to be devoted to the prosecution on a large scale of the researches on serum initiated by Prof. Behring. The *British Medical Journal* appropriately recalls the fact that several years ago Prof. von Behring gave the half of a French prize awarded to him, equivalent to a sum of 1000*l.*, in furtherance of serum research.

A NEW city branch of the Imperial Institute will be opened early in May for the display, to merchants, manufacturers, &c., of raw and manufactured products received, from time to time, from the colonies and from India, and for which it is desired to find openings in the British markets. Curators and other members of the Imperial Institute staff will attend at the office at stated times and by special appointment, to deal with inquiries and to assist in establishing or facilitating business relations with mercantile houses, &c., in the colonies and in India. The city branch will be in constant communication, by telephone and messengers, with the Imperial Institute, South Kensington.

EARLY in April, students of the Institution of Electrical Engineers will visit the Newcastle-on-Tyne district and inspect several works there. Among the places to be visited are the works and substations of the Newcastle Electric Supply Co. and of the Sunbeam Electric Lamp Co., the Elswick Works of Sir W. G. Armstrong, Whitworth and Co., the three-phase tramway system at Stockton-on-Tees, and the works of Messrs. Palmer's Shipbuilding and Iron Co.

WE are informed that at the meeting of the Connecticut Academy of Sciences on February 12, Prof. A. E. Verrill exhibited several remarkable photographs in natural colours taken direct from nature by a new process, just invented by Mr. A. Hyatt Verrill, of New Haven. One of these was a Bermuda landscape, in which the beautiful blue and green tints of the water, as well as the soft, creamy colour of the old stone Walsingham residence and the natural grey of the rocks, were well brought out. Three other plates were copies of water-colour drawings of groups of bright-coloured Bermuda fishes, taken from life by Mr. Verrill. The photographs were on paper, and were said to have been obtained by a purely photo-chemical process.

THE report of the council of the Scottish Meteorological Society, read at the general meeting of the Society on March 20, announces that the second volume of the Ben Nevis observations is approaching completion. This is the first of the three volumes, for the printing of which the Royal Societies of London and Edinburgh have each voted 500*l.* It contains the observations made at the Ben Nevis and Fort William Observatories from January 1888 to December 1892, and discussions connected with them. One of these discussions is by Mr. J. Aitken, F.R.S., on the dust of the atmosphere as observed on Ben Nevis and at various places in Scotland. For several years experiments with kites for meteorological purposes have been carried on near Edinburgh by Mr. John Anderson. He has now obtained a complete outfit, including an oil-engine of two and a quarter ($2\frac{1}{4}$) horse-power. It is proposed to test this kite, which in some respects has new features to recommend it, very thoroughly in the early summer. The outfit will be handed over to the ship of the Scottish Antarctic Expedition for use in the South Polar regions.

WE have received a reprint of a letter from Prof. A. Agassiz to Prof. E. S. Dana, dated Colombo, January 29, in which Prof. Agassiz announces the return of his expedition from an exploration of the Maldives, extending over several weeks. The general form of the plateau on which the atolls are situated has been determined and the channels between the lagoons carefully studied. The principal atolls in the middle of the group

are separated by shallow water, but towards the south the depths increase to nearly a thousand fathoms. Atolls are found in all stages of formation, including specimens of greater simplicity than have been found anywhere except on the Yucatan plateau. A preliminary report of the work will be issued as soon as the charts are completed.

IN a paper published by the Amsterdam Academy of Sciences, Prof. Eugene Dubois discusses the supply of sodium and chlorine by rivers to the sea. A large number of analyses of river-water are dealt with, and Prof. Dubois arrives at the conclusion that Sir John Murray's estimate of the amount of sodium delivered by rivers is much too high. The point is of special interest in relation to the attempts of Prof. Joly and others to estimate the age of the earth from chemical denudation. Prof. Dubois' results seem to indicate a period of the same order as that obtained by Lord Kelvin—twenty-four millions of years.

MR. J. BARCLAY, Birmingham, asks for an explanation of an effect he has observed, produced by refraction of air. While looking at a bookcase through the heated air rising from the chimney of a lighted lamp, the line of sight being a few inches above the top of the chimney, he noticed that one of the volumes appeared to project in front of the row in which it stood. Mr. E. Edser, to whom the observation has been referred, writes in reply:—"The illusion is obviously due to the refraction of light by a cylindrical column of heated air, which acts as a divergent cylindrical] lens. The refractive index of the air of the room may be taken, roughly, as equal to 1·0003. If the heated air rising from the chimney of the lamp has a temperature of 300° C., its refractive index would, roughly, be equal to 1·00015. At the interface between the cold and heated air, the effective refractive index would be equal to 0·99985. Assuming the lamp chimney (and therefore the column of heated air) to have a diameter of 1 inch, then the focal length of the cylindrical lens would be 0·00015. The distance of the book from the lamp was about 8 feet, or (say) 100 inches. Seen through the column of heated air, the distance v of the book from the lamp is given by the equation $1/v - 1/100 = 0{\cdot}00015$, from which v is found to be 99 inches. The book thus appears about an inch in front of its true position, as observed by Mr. Barclay."

WE congratulate our Norwegian contemporary, *Naturen*, on having completed the first quarter of a century of its struggle for existence in a country of only two and a quarter millions of inhabitants. It is published in Bergen, where it was founded in 1877 by Dr. Hans Reusch, then an assistant in the Geological Survey of Norway, of which he is now director. In spite of many difficulties, *Naturen* gradually gained ground at a time when old and excellent journals such as *Tidskrift for populaere fremstillinger* and *Naturen og mennesket* (both published in Denmark) were discontinued. In 1881 Dr. Reusch went abroad for some years and handed over *Naturen* to Herr Carl Kraft, who conducted it on the same lines and against the same difficulties until 1886. In January 1887 the journal became the property of the Museum in Bergen, which continued its publication under the editorship of its director, Dr. I. Brunchorst, and in 1893 it received a yearly Government grant of Kr. 1000 (= 55*l.* 10*s.* 3*d.*), on condition that 400 copies are supplied monthly at half price to State schools and public libraries, so that poorly paid teachers and others in remote districts may have access to its pages. In its first number for 1902, in which it celebrates the commencement of the twenty-sixth year of its existence, we are presented with the portraits of its first two editors. The number also contains articles by the three contributors to its first number in 1877, viz. Dr. H. Reusch, Herr I. Sparre Schneider and Prof. Geelmuyden. We wish the journal a long and prosperous life.

IN a lecture lately delivered before the Norwegian Geographical Society by Captain R. Amundsen, the author gave an account of the proposed exploring expedition to the magnetic North Pole. Captain Amundsen was first officer of the *Belgica*, which sailed for the Antarctic in August 1897 with the view of determining the exact locality of the magnetic South Pole, and it was while that ship lay fixed in the drift-ice west of Graham Land that the idea was conceived of exploring the magnetic North Pole. For the contemplated expedition, the *Gjöa*, one of the strongest and best sailing-vessels of the Arctic fleet, has been purchased at Tromsö. In 1831, Sir James Clark Ros reached a position where the dipping-needle was only deflected one minute from an absolutely vertical position, but the question has been raised whether the magnetic pole is actually only a point or whether the peculiarity of the needle assuming a vertical position extends over a large area, and, further, whether the magnetic pole changes its position. With the object of solving these two questions, Captain Amundsen will sail in the spring of 1903. The *Gjöa* is to be fitted with a petroleum engine and will carry a crew of seven men. A travelling magnetometer is under construction at the Deutsche Seewarte, and will resemble that used on board the *Fram*. A dipping-needle is being constructed in London, and will be examined at the observatory of the National Physical Laboratory. It is proposed to take magnetic observations as frequently as practicable, to leave the ship either at Matty Island or King William Land, and as soon as the severest part of the winter is over to continue the journey with the sledges to the place on Boothia reached by Ross.

WE have received a copy of Mr. C. E. Stromeyer's paper on explosions of steam pipes due to water-hammers, read before the Manchester Literary and Philosophical Society. The paper deals both with the causes of these explosions and with the forces which come into play when they occur. At the meeting Mr. Stromeyer made two sets of experiments with water in glass pipes. The first illustrated those accidents which are caused when the steam pipes are so arranged that water may find a lodgment over the boiler stop valve. When opening this valve, the steam pressure shoots the plug of water along the pipe until it strikes and shatters the engine stop valve, if this happens to be left partly open. The other experiment showed that if near the boiler stop valve there is an L pipe in which water can lodge while steam is in the main pipe above the vertical leg, then by draining away this water, which has, of course, to be done before starting the engine, steam is admitted to the horizontal leg and most violent steam-hammer blows occur, which have been the cause of many explosions. In the theoretical part of the paper, Mr. Stromeyer gives a proof that the velocity of a pressure wave is the same as the velocity of sound, which has an important bearing as showing that both undulatory and angular sound waves travel with the same speed. Then as regards the pressure exerted by an elastic body like water when it suddenly comes to rest, he explained that a pressure wave travels from the front end of the water column to the back end, and that the back end, or in fact any part of the water column, continues to move forward with its original velocity as long as it does not feel the wave of pressure. The arrested (pressed) water column is, therefore, shorter than the moving one. The ratio of the amount of shortening to total length is the ratio of original velocity (V) of the whole column to the pressure velocity (W). By multiplying this ratio by the elasticity of water (E) we get the pressure $P = E\,\dfrac{V}{W}$. Thus a plug of water only 6 inches long propelled through a distance of only 2 feet under a pressure of 15 pounds would on being suddenly arrested exert a pressure of 6400 pounds.

OUR contemporary the *Electrical Review* of New York celebrated on February 15 the twentieth anniversary of its publication. The greater part of a special issue is devoted to retrospective articles on the development of the different branches of the industry during the past twenty years. A facsimile reproduction of the first page of the first number shows that the original title of the journal was the *New York Review of the Telegraph and Telephone*, which sufficiently indicates the position of electrical engineering at that time. In 1882 the incandescent lamp was only just developed to a practical article; towards the end of the year the first central generating station was opened by Mr. Edison in New York. The first attempts at electric traction were just being made, and industrial electrochemistry had not advanced further than electroplating and a little copper refining. It has become, perhaps, hackneyed to remark on the rapid development of electrical engineering, but it is pleasant to be reminded occasionally in so striking a fashion how very great the rapidity has been. One of the most interesting features of the issue under consideration is the reproduction of engravings from early numbers showing some of the first commercial machines, and the comparison of these with the process blocks of the enormous engines and dynamos now in use. Altogether we can congratulate the paper on a very attractive and instructive number.

OWING to recent excavations in Hull, a large number of seventeenth century tobacco pipes have been discovered; these have been figured and described by Mr. T. Sheppard, the curator of the Hull Museum, in one of the useful penny guides, to another of which, on an ancient model of a boat, we drew attention a short time ago. This handbook will prove of value, as little is known about early clay pipes and their makers.

IN the thirty-fifth report on the Peabody Museum of American Archæology and Ethnology of Harvard University, we have a very satisfactory record of the research and field work accomplished during the year 1900–01. There were seven expeditions during that period to various parts of North and Central America for the purpose of studying languages, customs and archæology, and one graduate has done some valuable work in Syria. The collections have increased so greatly that the existing museum accommodation is quite inadequate; doubtless this will soon be remedied, as wealthy Americans are always ready to help deserving institutions that do their best.

WE have often drawn attention to the valuable *Bulletins* of the Madras Government Museum, and the current number (vol. iv. No. 2) fully sustains the reputation of the series. Mr. Edgar Thurston demonstrates an unexpected occurrence of brachycephaly among certain Dravidian tribes in the Bellary district of the Madras Presidency, where 37·8 per cent. (among 419 subjects examined) have a cephalic index of above 80, the average being 78·9 as opposed to an average index of 73·8 in the southern districts of the Presidency. We are pleased to find that Mr. Thurston will now study this problem. Mr. T. Ranga Rao is the author of an interesting paper on the Yánádis of the Nellore district (see p. 437), which was written as a thesis for the M.A. degree examination of the Madras University; in this recognition of ethnology the Madras University is in advance of those in the mother country. Among the "Miscellanea" are notes on the couvade, albinos, earth-eating, weighing beams, and other matters of interest pertaining to the ethnology of southern India.

NO. 6 of the *Sitzungsberichte* of the Vienna Academy for 1902 contains an abstract of the third part of Franz Baron Nopesa's work on the dinosaurian remains from Siebenburgen. This fasciculus is devoted to the description of the skull of the iguanodont known as Mochlodon, and also of dermal plates described under the name of Onychosaurus. In a second communication the author discusses certain European Cretaceous armoured dinosaurs, such as Struthiosaurus, Acanthopholis and Polacanthus, which he believes to be closely related to the remarkable horned Ceratopsidæ of North America.

IT is most satisfactory to learn, from an article contributed to the March number of the *Zoologist* by Mr. John Gurney, that spoonbills are making the mud-flats of Breydon Broad, Norfolk, their regular summer resort, from two to four of these beautiful birds having frequented this locality from the early part of April till the end of July. An avocet was also seen there on one occasion. These gratifying results are entirely due to protection; but Mr. Gurney adds that "unless the Breydon Wild Birds' Protection Society receives more pecuniary support than it has had in the past, it will be unable to continue to carry on its good work." In a rich county like Norfolk there ought to be no difficulty in obtaining the necessary funds. Out of the fifteen Spanish bustards turned down near Thetford in 1900, only two pairs remain, and these wandered on one occasion nearly as far as Newmarket. Among rare birds recorded in Norfolk during the past year, Mr. Gurney mentions the golden oriole, orange-legged hoby, woodchat, roller, Tengmalm's owl and Caspian tern.

IN his address to the thirteenth annual meeting of the Association of Economic Entomologists, held at Denver, Colorado, in August last (of which a report appears in *Bulletin* No. 31 of the Entomological Division of the U.S. Department of Agriculture), Mr. G. P. Gillette took for his subject the life-history of the codling-moth. One of his objects was to show the imperfection in our knowledge of the history of even the most common insects; and since, next to the "two-lined locust," the codling-moth is the species which occasions the greatest loss to cultivators in Colorado, the importance of a full knowledge of its habits can scarcely be overrated. Until quite recently, entomologists held the belief that the moth lays its eggs in the calyces of apples; the fruit-growers knew this to be an error, and in consequence have, unfortunately, somewhat lost confidence in the work of the Division. A special subject of investigation has been the number of broods annually produced by this insect. In Colorado, where the species is definitely known to be double-brooded, the habits of the moth are probably very different from those in the more eastern districts, and one of the main objects was to determine whether in the warmer parts of the country, where more tender fruits are grown, the annual number of broods might not be greater.

MESSRS. BLACKIE AND SON contemplate a re-issue of Kerner's "Natural History of Plants," a work which in its English form is identified with the name of Prof. F. W. Oliver. The new edition, which will be issued at a considerably reduced price, will be substantially a reprint of the original English edition, with a few necessary alterations and corrections.

THE "Class List and Index of the Periodical Publications in the Patent Office Library," lately published by the Patent Office (Bibliographical Series, No. 5), is a well-arranged catalogue of journals, reports and other periodical publications of interest to students of pure and applied science. The reports of scientific and polytechnic societies and the scientific and technical journals are subdivided locally; they are also classified according to subjects. There are in the list 2563 works, distributed under 356 classes and representing about 39,680 volumes.

TWO catalogues of scientific apparatus which have recently been received show that the needs of teachers and investigators of physical science are well supplied by instrument makers. One

of the catalogues shows apparatus made by Messrs. J. J. Griffin and Sons for the purposes of instruction in sound, light and heat in schools and colleges. Among the new and ingenious devices contained in the catalogue we notice simple apparatus for the determination of the coefficient of linear expansion, the determination of relative conductivities, and a model theodolite. To make the catalogue of permanent use in the laboratory, tables are given of physical constants frequently required, and of logarithms, anti-logarithms and trigonometrical functions. The new catalogue of physical and electrical apparatus made by the Cambridge Scientific Instrument Company contains many instruments of precision not found in the lists of other instrument makers. For instance, a comparator and cathetometer combined, which can be used in a vertical or horizontal instrument, is described in the catalogue, and also geometric tripod stands, which can be so arranged as to form a stand of any desired height. Both these appliances were designed by Prof. C. V. Boys, and have not been illustrated previously. Other noteworthy instruments are a chronograph for laboratory use and the "Cambridge" standard coils, which are wound with bare platinum silver wire round a stout mica frame supported by a brass carrier. The coils are contained in a glass case with an ebonite top and are immersed in insulating oil. This arrangement ensures the coil being at the true indicated temperature, as there is no lagging due to paraffin wax or silk covering.

THE additions to the Zoological Society's Gardens during the past week include a Wedge-tailed Eagle (*Aquila audax*) from Australia, presented by Mr. Aubrey Richardson; two Spotted Turtle Doves (*Turtur suratensis*), a Barred Dove (*Geopelia striata*) from India, presented by Mr. L. Ingham Baker; a Common Bluebird (*Sialia wilsoni*) from North America, presented by Miss L. B. Dyar; five Prjevalsky's Horses (*Equus prjevalskii*) from Northern Mongolia, an Egyptian Jerboa (*Dipus aegypticus*) from North Africa, a Raven (*Corvus corax*), a Lapwing (*Vanellus vulgaris*), European, a Red-fronted Amazon (*Chrysotis vittata*) from Porto Rico, a Lesser Sulphur-crested Cockatoo (*Cacatua sulphurea*) from Moluccas, two Californian Quails (*Callipepla californica*) from California, five Yellow-winged Sugar-birds (*Coereba cyanea*), three Brazilian Tortoises (*Testudo tabulata*) from South America, a Long-necked Chelodine (*Chelodina longicollis*), a Bearded Lizard (*Amphibolurus barbatus*), a Gould's Monitor (*Varanus gouldi*), a Lace Monitor (*Varanus varius*) from Australia, twenty-four sharp-headed Lizards (*Lacerta dugesi*) from Madeira, deposited.

OUR ASTRONOMICAL COLUMN.

ASTRONOMICAL OCCURRENCES IN APRIL.

April 2. 4h. Saturn in conjunction with moon. Saturn 5° 15′ S.

3. 9h. Jupiter in conjunction with moon. Jupiter 5° 53′ S.

4. 8h. 46m. Minimum of Algol (β Persei).

8. Sun eclipsed, invisible at Greenwich.

9. 15h. 51m. to 20h. 35m. Transit of Jupiter's Sat. IV.

10. Saturn. Outer minor axis of outer ring = 13″·96.

10. 16h. Ceres in conjunction with moon (Ceres 0° 23′ N.).

11. 9h. 36m. to 10h. 15m. Moon occults δ^3 Tauri (mag. 4·2).

12. 11h. 23m. to 12h. 11m. Moon occults 119 Tauri (mag. 4·6).

14. 12h. 36m. to 13h. 9m. Moon occults 68 Geminorum (mag. 5·0).

15. Venus. Illuminated portion of disc = 0·435, of Mars = 1·000.

15. 11h. 47m. to 12h. 17m. Moon occults 27 Cancri (mag. 5·6).

21. 11h. 46m. to 12h. 52m. Moon occults α Virginis (mag. 1·2).

April 22. 5h. 0m. to 8h. 45m. Moon eclipsed, partly visible at Greenwich. Moon rises at 7h. 5m. totally eclipsed.

23. 12h. Mercury in conjunction with Mars. Mercury 0° 40′ S.

23. 12h. 30m. to 16h. 12m. Transit of Jupiter's Sat. III.

24. 10h. 28m. Minimum of Algol (β Persei).

25. 10h. 53m. to 12h. 7m. Moon occults B.A.C. 5580 (mag. 5·7).

25. 12h. Venus at greatest elongation, 46° 12′ W.

26. 10h. 51m. to 15h. 40m. Transit of Jupiter's Sat. IV.

28. 16h. 20m. to 17h. 44m. Moon occults ρ^1 Sagittarii (mag. 3·9).

29. 14h. Saturn in conjunction with moon. Saturn 5° 20′ S.

ORIGIN OF DISTURBANCE IN CORONA, MAY 17–18, 1901.—*Bulletin* No. 18 from the Lick Observatory is devoted to the discussion of more detailed examination of the photographs obtained during the total solar eclipse in Sumatra, which showed evidence of a marked disturbance in a certain region of the corona. A set of positives on glass from solar negatives taken at Dehra Dûn, India, for the Solar Physics Committee, have since been received from the Astronomer Royal, giving exact records of the solar surface on May 17, 18, 19, 20, 21, 22, 26 and 28, 1901. The photographs of May 17 and 18 show no evidence of spots or other active features, but that for May 19 shows a medium-sized spot just passed into view round the east limb. On the 20th, this is seen to be followed by a group of smaller spots, surrounded on all sides except the west by a large area of faculæ. This group of small spots shows conspicuous changes from day to day.

The positions of the spot on the plates of May 19 and 28 were measured, and from the reduced values its probable position on the day of eclipse was computed. It would be on the opposite side within 4° of the limb. The position angles of the spot as projected on the limb and the apex of the coronal disturbance are practically identical. As, moreover, both the sunspot and the coronal disturbance appear to have had the same latitude, it can hardly be doubted that this unusual appearance in the corona was in reality immediately above the group of sunspots and faculæ, and that it had its origin in the same disturbance of the solar surface. In view of this conclusion, an attempt was made to determine if any measurable displacement of any of the coronal masses had occurred during the interval of about five minutes, but no certain indication of such motion could be detected. In this connection, however, the interval of one and a half hours between the times of eclipse in Mauritius and Padang should render a comparison of the negatives secured at the two stations valuable.

FOUCAULT'S PENDULUM.—An interesting announcement is made in the March number of the *Bulletin de la Société Astronomique de France* to the effect that a movement is being started among the astronomical authorities in Paris to arrange for the repetition of Foucault's famous experiment at the Panthéon, which was interrupted in 1851. No definite arrangements are yet settled, but it is hoped this majestic demonstration of the rotational movement of the earth will be successfully installed with all the advantages of modern refinements in instrumental construction.

A CONVENIENT TERMINOLOGY FOR THE VARIOUS STAGES OF THE MALARIA PARASITE.[1]

I HAVE found it necessary in labelling a series of models of the malaria parasite in the Central Hall of the Natural History Museum to use as simple and clear a terminology as possible. I think that this terminology will be found useful by others who are perplexed by such terms as "sporozoites," "blasts," "ookinetes," "schizonts," "amphionts" and "sporonts"—terms which have their place in schemes dealing with the general morphology and life-history of the group Sporozoa, but are not, as experience shows, well suited for immediate use in describing and referring to the stages of the malaria parasite.

It is necessary to treat the malaria parasite from the point of view of malaria; that is to say, to consider its significant phases

[1] By Prof. E. R. Lankester, F.R.S. Read before the Royal Society on March 6.

to be those which it passes in the human blood. In reality its mature condition and most important motile, as well as its most prolific reproductive, phases are passed in the body of the mosquito.

(1) The malaria-germ which is brought by the stab of the Anopheles into the human blood-vessels is a reproductive particle, a *spore*. It is needle-like in shape, and might be named in reference to its form (*e.g.* oxyspore or raphidiospore), but the most important fact about it for description and comparison is that it has been formed *outside* the human body, and is introduced as a strange element into the human blood by the agency of the mosquito. I therefore call it the EXOTOSPORE.

(2) The Exotospores (probably as many at a time as forty or fifty) enter the blood by the agency of the mosquito's stab and immediately penetrate, each one, a red corpuscle. The history of this process has not been observed. As soon as it has entered a red corpuscle the exotospore loses its needle-like shape and becomes amœbiform. I apply to it the name I proposed some years ago for similar amœbiform spores in other Protozoa, namely, AMŒBULA ("Encyclopædia Britannica," article "Protozoa").

(3) The Amœbula exhibits amœboid movements within the red corpuscle, enlarges and finally breaks up into spherical spores, which are liberated with destruction of the red corpuscle. It seems to me unnecessary to have a special name for the star-like or other condition of the Amœbula when in course of breaking up into spores; but the spores so produced require a special name which shall emphatically distinguish them from the Exotospores. I call them the ENHÆMOSPORES, in reference to the fact that they are produced by a process of division which occurs *in* the blood of the malaria-stricken human being.

(4) The Enhæmospores penetrate fresh red blood-corpuscles, and after a certain growth as amœbulæ break up into a new crop of Enhæmospores, by which the infection of the red corpuscles is extended. This process appears to go on for several generations and for a varying duration of time. But owing to conditions and at a period of the infection which has not been precisely ascertained, some (or all?) of the amœbulæ derived from Enhæmospores cease to break up into spores. Instead of carrying out that process they enlarge, and in the case of the æstivo-autumnal parasite (*Laverania praecox*) become sausage-shaped or, as it has been termed, crescent-shaped. This change of form is accompanied by a destruction of the red corpuscle and the formation of granules of dark pigment within the parasite. It seems best to term this phase the "CRESCENT" or "CRESCENT-SPHERE," the latter term being applicable to those species in which the form is not markedly crescentic.

(5) The crescents or crescent-spheres remain quiescent in the human blood. They are, however, of two different natures—male and female. It is not possible to distinguish with any certainty the male from the female crescents whilst they remain in the human blood-vessels. But it is these bodies which are destined to be swallowed by the Anopheles mosquito and to carry on further the life-history of the parasite.

The crescents are therefore the sexual phase of the parasite. When the crescents are swallowed by a mosquito (of an appropriate species), they undergo two different modes of development, determined by the fact of their sex. Both sexes become spherical, and may now be called respectively "EGG-CELL" and "SPERM-MOTHER-CELL."

From the periphery of the SPERM-MOTHER-CELL, now floating in the mosquito's stomach, there are developed with surprising rapidity six or seven SPERMATOZOA, which for a time remain attached to the residual mass (or SPERM-BLASTOPHOR) of the sperm-mother-cell. Complete cytological study of this development is still wanting, but it appears that the spermatozoa are true spermatozoa, like those of the higher animals, and have the same relation to the mother-cell from which they develop as is the case in such an animal as the earth-worm.

The EGG-CELL, now also floating in the mosquito's stomach, apparently gives rise to one, and possibly to two, polar bodies, but the observations on this point are, as yet, insufficient.

Fertilisation of the egg-cell now takes place in the gnat's stomach. A single spermatozoon penetrates and fuses with each egg-cell.

The fertilised egg-cell is spoken of as a "zygote"; it is also described as the sexually produced embryo.

(6) The ZYGOTE OR SEXUALLY PRODUCED EMBRYO remains unicellular, but increases in size and becomes pyriform. It exhibits active movements of expansion and contraction in the line of its long axis, and also a quick movement of its narrower end alternately to either side. This is the largest growth of the individual cell attained to in the series presented by the life-history of the malaria parasite. It has been called "vermiform" and "vermicule" (Ross), and I adopt this name for it, viz. the VERMICULE. The vermicule is the dominant individual form in the history of the malaria parasite, endowed with greater size, power and activity than other phases. It corresponds, not only in this respect, but also in its position in the life cycle, to the large often active cells of the Gregarinidea, which I proposed some time ago to call the Euglena-phase ("Encyclopædia Britannica," article "Protozoa").

It is worthy of note that in the size and activity of the vermicule, the Hæmaosporidia—the order of Sporozoa which embraces the malaria parasite—come nearer to the Gregarinidea than they do to the Coccidiidea, though in the existence of a sexual generation absent in Gregarinidea they agree with the Coccidiidea.[1]

The vermicule now pushes its way through the tissues of the gnat's stomach and in the blood sinuses outside the stomach becomes spherical. It enlarges and nourishes itself on the insect's blood, and forms a spherical CYST, or structureless transparent envelope. This cyst is destined to enlarge, with vast increase of its living contents.

The living cell within the cyst breaks up by a definite process to form eventually an immense number of exotospores, the stage with which the present description commenced. The CYST would most conveniently be called a "sporocyst," since, as so often happens in Protozoa, it is formed purely and simply in relation to the quiescence of the organism and its division into numerous reproductive spores. Unfortunately, the word "sporocyst" has been employed recently by writers on the Sporozoa for the small capsules containing one or two to eight elongated spores which used to be called "pseudonaviculæ," and are formed *within* such larger cysts as that now in question. The word "cyst" should have been reserved for the larger more general protective envelope, and the "pseudonaviculæ" might have been called "sporo-thekæs." In any case, I think we may call the cysts in which the vermicules of the malaria parasite enclose themselves "SPORE-CYSTS" or "SPORE-FORMING CYSTS." The name "oocyst," applied to them by some writers, is simply misleading.

(7) The spore-cysts lying outside the stomach wall of the mosquito bathed in the insect's blood receive abundant nourishment. The single-celled vermicule enclosed undergoes rapid changes; it increases greatly in volume and breaks up by normal cell division (? the earliest steps have yet to be studied) into a number of SPORE-MOTHER-CELLS. In the process of this division and the later stages of the final development of the "spores" (exotospores), the "spore-forming cyst" increases in size to twenty times its initial diameter.

The spore-mother-cells are set closely together in the cyst; they are of polygonal shape, owing to pressure, and each has its nucleus. Finally they give rise, each spore-mother-cell, to a crop of filiform spores (exotospores) which have the same relation to the spore-mother-cell as spermatozoa have to a sperm-mother-cell, viz., they form on the outside of the spore-mother-cell as outstanding processes, carrying away all the chromatin of the mother-cell and leaving in the centre or to one side a "residuary body," a "spore blastophore" similar to the "sperm-blastophore" of spermatozoon-development.

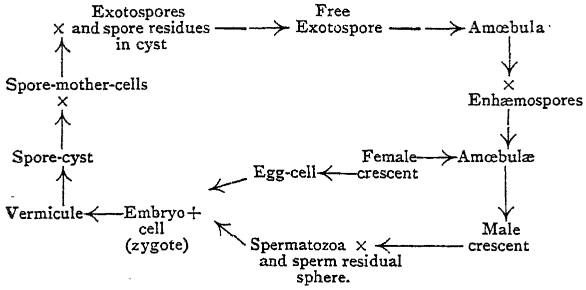
Thus we are brought back to the needle-like exotospores with which we started.

The spore-holding cysts burst and liberate the exotospores into the blood of the mosquito. Thence they readily pass into the ducts of the salivary gland, and so are conveyed by the mosquito's stabbing beak into human beings. A point in this connection is the definite ejection by the mosquito of the secretion of its salivary gland into the punctured wound which it makes in the human skin. There can be no doubt that such an ejection takes place. The leech ejects a secretion on to the wound caused by its bite which has the property of preventing the coagulation of the blood. It is possible that the mosquito and other blood-sucking flies may use the salivary secretion for the same purpose. It is obvious that unless there were some injection into the wound on the part of the fly, the chances of

[1] A sexual phase has been described in the Gregarine Stylorhynchus by Léger since this paper was written. It occurs at an unexpected point in the cycle: two encysted full-grown "Sporonts" are stated to produce the one egg-cells the other spermatozoids.

infection of the bitten animal by the parasites carried by mosquitoes or tzetze fly would be very small.

Our cycle of forms with the names here made use of may be written as below. The sign × is used to indicate fissile multiplication, and + to indicate fusion, while → merely indicates continuity.



I also give a list of the names here used with reference to the occurrence of the forms indicated in man or in gnat and an indication of the corresponding stages in a Gregarina and a Coccidium. In the column belonging to Coccidium I have employed the generalised physiological nomenclature accepted by special students of the Sporozoa (Schaudin, Lühe, &c.).

power will be given to have that limit raised by provisional order. Boroughs already possess a certain jurisdiction over technical education, and have a rate of 1*d.* to work upon. It is not proposed to deprive any borough with a population above 10,000, or any urban district with a population above 20,000, of that jurisdiction. The councils of these boroughs and urban districts may, if they choose, become the absolute authority over primary education. They would retain their existing powers over technical education, and would become the authority for secondary education concurrently with the county council. But whether the schools in a district are voluntary or rate erected, the local educational authority created by the Bill will in future be the absolute master over all secular education. London is excluded from the operation of the Bill. The adoption of the elementary education portion of the measure would, for a time, be optional.

MR. H. BRERETON BAKER, M.A., late scholar of Balliol College, Oxford, has been elected by the governors of Dulwich College to be headmaster of Alleyn's School, Dulwich. Mr. Baker, who has had several years' scholastic experience as senior science master in Dulwich College, is well known as a chemist of real distinction, whose important papers in the *Philosophical Transactions* and the *Journal* of the Chemical Society on the remarkable influence of traces of moisture in facilitating chemical action have attracted well-deserved attention. Physical science has long formed a prominent part of

Malaria.	Coccidium.	Gregarina.
1. Exotospore, free in human blood ... ... ("Blast" of some authors.)	Sporozoite	Sporozoite. (Filiform young.)
2. Amœbula, in red corpuscles	Schizont	Amœbula.
3. Enhæmospore, ditto, and in blood	Merozoites, formed by schizogony.	
4. Crescent, in human blood	Gametocytes	
a. Male	Microgametocyte	
b. Female	Macrogamete	Schizogony rare; sexual stages NOT OBSERVED and probably WANTING.
5. Sperm-mother-cell, in gnat's stomach	Microgametocyte	
6. Egg-cell, in gnat's stomach	Macrogamete	
7. Spermatozoon, in gnat's stomach	Microgamete	
8. Zygote or embryo-cell, in gnat's stomach	Young oocyst (sporont)	
9. Vermicule, in gnat's stomach	WANTING ... ... (Called "ookinete" or "kinetosporont" in the nomenclature of this column.)	Full-grown motile "gregarine." (Euglenoid phase.)
10. Spore-cyst, in blood-sinus outside gnat's stomach	Older (but not larger) oocyst or sporont	Cyst enclosing one or two full-grown sporonts.
11. Spore-mother-cells in cyst, in blood-sinus outside gnat's stomach	Sporoblasts (sporogony)	Sporoblasts. (? Conjugation in *Lankesteria Ascidiae.* Spermatozoa and ova in Stylorhynchus.)
12. Exotospores in cyst, in blood-sinus outside gnat's stomach	Sporozoites enclosed in small groups in sporocysts within the bigger oocyst.	Sporozoites enclosed in capsules, called "pseudonaviculæ" or "sporocysts."
21. Free exotospores, in gnat's salivary duct	Free sporozoite	Free sporozoite.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

THE proposals of the Government with respect to education in England and Wales were described in the House of Commons by Mr. Balfour on Monday, and after a discussion, leave was given for the introduction of the Government Education Bill. It is proposed that in future there shall be one authority for education, primary, secondary, and technical; and that this authority, being responsible for a heavy cost to the ratepayers, shall be the rating authority for the district. Explaining the broad outlines of the measure, Mr. Balfour stated that the education authority will be the county council in counties and the borough council in county boroughs. They will work through committees appointed under schemes which will have to be approved by the Education Department. A majority of a committee at least is to be appointed by the council. The other members are to be nominated, and to be persons experienced in education. Wales, which has a secondary education authority already, is to be permitted either to retain that authority or to substitute for it the authority proposed in the Bill. With regard to secondary education, the provisions of the measure are practically identical with those embodied in the Bill of last year. County councils and borough councils are to have a 2*d.* rate to work upon, and as in many places that will be insufficient,

the course at Alleyn's School, which possesses physical and chemical laboratories that are probably not surpassed by those of any school in the country It will be a matter of interest to scientific men that at least one school in the kingdom should be, not only well provided with laboratory accommodation, but should have at its head a man of acknowledged scientific reputation.

SIR PHILIP MAGNUS will preside at a public meeting to be held in connection with the conference of the National Association of Manual Training Teachers at Manchester on Easter Tuesday, April 1.

THE Government of India has had under consideration the improvement of the existing system of education of Europeans and Eurasians, and the Local Governments have been asked for an expression of their views upon the subject. Meanwhile (says the Allahabad *Pioneer Mail*) a small committee of educational officers has been appointed to examine and revise the Bengal Code of Regulations for European Schools, in the hope that it may be found possible to render it suitable for adoption throughout India. The Secretary of State has accepted the proposal of the Government of India to create an appointment of Director-General of Education in India, and Lord George Hamilton has selected Mr. H. W. Orange to fill the post.

AT a meeting of the Edinburgh Mathematical Society on March 14, the following resolutions in regard to the teaching of elementary mathematics were agreed to:—(1) That the primary object in teaching elementary mathematics is to afford a mental training to the pupil. The commercial, technical or professional applications of the subject are of secondary importance in general education. (2) That there should be no undue haste to begin the study of the calculus with a view to its practical applications. (3) That pupils should not be encouraged in the unscientific practice of placing dependence on rules or formulæ which they do not understand. (4) That, in teaching any branch of mathematics, concrete illustrations and verifications including experimental, graphical and other methods should, wherever practicable, accompany theory. (5) That in examinations particular methods of solution or demonstration should not, as a rule, be demanded, *e.g.*, the use of algebra should not be prohibited in answering questions in arithmetic or geometry. (6) That there should not be imposed upon schools in any branch of mathematics a syllabus which does more than indicate the order in which the main divisions of a subject are to be taught.

DR. D. C. GILMAN'S reminiscences of the foundation and early days of the Johns Hopkins University, given in the current number of *Scribner's Magazine*, contain several interesting particulars concerning men connected with it. Johns Hopkins left his fortune to be divided between a university and a hospital, the two to be united in the promotion of medical science. As the capital for the university was thus provided by a single individual, there were no bodies to interfere with its plans, and no public or treasury to conciliate. Given the idea and the funds, all that had to be done was to produce the plan of an institution which should aim at having national influence, and should take to Baltimore, as teachers and students, the ablest minds that could be attracted there. Rowland was an assistant instructor in the Rensselaer Polytechnic Institute when Dr. Gilman heard of him from General Michie, and the following conversation occurred:—"What has he done?" I said. "He has lately published an article in the *Philosophical Magazine*," was his reply, "which shows great ability. If you want a young man you had better talk with him." "Why did he publish it in London," said I, "and not in the *American Journal?*" "Because it was turned down by the American editors," he said, "and the writer at once forwarded it to Prof. Clerk Maxwell, who sent it to the English periodical." When Dr. Gilman had seen Rowland and reported upon his rare powers to the trustees in Baltimore they said at once, "Engage that young man and take him with you to Europe, where he may follow the leaders in his science and be ready for a professorship." This was done; and the result is well known. Huxley gave the inaugural address, but he had to deliver it from memory, as he could not read the flimsies with which the reporters to whom he had dictated the lecture on the previous day had provided him. After this opening without music, prayer or other benediction came the storm of indignation from the religious papers. Referring to the opening, a Presbyterian minister wrote to a friend:—"It was bad enough to invite Huxley. It were better to have asked God to be present. It would have been absurd to ask them both. I am sorry Gilman began with Huxley. But it is possible yet to redeem the University from the stain of such a beginning." It took some years for the prejudice to wear away, but eventually the idea of an undenominational university controlled by laymen was accepted as reasonable, and Johns Hopkins' foundations became renowned as places of freedom and progress.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, January 30.—"The Distribution of Magnetism as Affected by Induced Currents in an Iron Cylinder when Rotated in a Magnetic Field." By Ernest Wilson, Professor of Electrical Engineering, King's College, London. Communicated by Sir W. H. Preece, F.R.S.

One object of this research was to investigate the effect which induced currents have upon the distribution of magnetism in an iron cylinder when rotated about its longitudinal axis in a magnetic field, the direction of which was normally at right angles to the axis of rotation. The variables dealt with were the total flux of magnetism between the poles of the magnet, and the speed of rotation of the cylinder. By threading insulated copper conductors through holes drilled in a plane containing the longitudinal axis, E.M.F.'s due to the rate of change of induction at different depths have been observed, and therefrom the intensity of induction has been found. The cylinder had a diameter of 25·4 cms., and its length was 25·4 cms. It was rotated by aid of a worm and worm wheel. Periodic times of 360, 180, 90, 45 and 22·5 seconds have been dealt with, and the normal induction density B in the cylinder has been varied from about 170 to 21,000 C.G.S. units per sq. cm.

With small magnetic force, and a periodic time of 45 seconds, the value of B at the centre of the cylinder is important as compared with its value at the surface, and the phase-displacement between the two is relatively small. With intermediate magnetic force, corresponding to high average permeability in the iron, the value of B at the centre became relatively small, accompanied by considerable phase-displacement. In fact, with 22·5 seconds periodic time, B at the centre was totally reversed in sign with regard to B at the surface, or the lag was 180°. With large magnetic force, B at the centre again became important, and the phase-displacement was again small. With a periodic time of 360 seconds, the disturbances above described still existed, but they were small. Similar effects to the above were observed in the case of an iron cylinder subjected to alternating magnetic force.

The conclusion was that with an alternating magnetic force applied axially to a cylinder of given diameter, the effects were more severe than in the same cylinder (of length equal to diameter) when rotated in a magnetic field as above described at the same frequency, and for corresponding values in the surface induction density. The results of these experiments were applied to similar cylinders of different dimensions by an application of the law of squares. The effects of induced currents in the armature of a certain class of induction motor were dealt with. It is shown that plates of iron 0·1 cm. thick experience no serious deviation from uniform distribution when rotated in a magnetic field, the direction of which was in the plane of the plate, at frequencies lower than about 180. Referring to Lord Kelvin's computation that the earth's magnetism is travelling round the earth in the direction of the sun with a periodic time relatively to the earth of 960 years, it is pointed out that in a cylinder similar in all respects to the one experimented upon, but having a diameter equal to that of the earth, a periodic time of 960 years would produce similar magnetic and electric events as would be observed in the above cylinder if it could be rotated with a periodic time nearly two million times as fast as the fastest speed in these experiments. On the other hand, with a cylinder 0·0000001 cm. diameter, 7×10^{14} revolutions per second would be required to produce the disturbances observed in these experiments.

March 6.—"The Differential Equations of Fresnel's Polarisation-vector, with an Extension to the Case of Active Media." By James Walker, M.A. Communicated by Prof. Clifton, F.R.S.

In many problems of optics we require the differential equations that the polarisation-vector has to satisfy, and the surface conditions that subsist at the interface of different media. These may be deduced from the principle of interference combined with the experimental laws of the propagation of light, without making any assumption respecting the character of the ether and the nature of the luminous vibrations. In crystalline media, Fresnel's theorem of the ellipsoid of polarisation affords the required relations between the wave-velocity and the directions of the wave-normal and of the polarisation-vector; in the case of active media, extensions of this theorem lead to similar equations giving the wave-velocity in terms of the direction-cosines of the wave-normal and the complex direction-cosines of the vector of a stream of elliptically polarised light. The differential equations are then deduced by applying the principle of interference. The surface conditions are obtained by assuming that the transition between two media takes place by a rapid continuous change of their properties and that the differential equations hold within the region of variation.

Royal Astronomical Society, March 14.—Dr. J. W. L. Glaisher, president, in the chair.—The secretary read a paper by Dr. Mitchell, of New York, on the flash spectrum at the Sumatra eclipse of May, 1901. Mr. Fowler gave reasons for doubting the correctness of Dr. Mitchell's view that the flash spectrum represents the upper portion of the layer of gas which, by absorption, gives the Fraunhofer lines.—A paper by Prof. Barnard on Nova Cygni, 1876, was partly read.—Mr. Maw presented a series of double star measures made by him in the

years 1899–1901.—The Astronomer Royal presented a paper on new variable stars found at the Royal Observatory during the measurement of plates for the Astrographic Catalogue, and also a series of measures of double stars made at Greenwich with the 28-inch refractor. Prof. Turner described an instrument for rapidly comparing two star plates of the same region, and Mr. Lewis spoke upon the orbit of δ Equulei.—Mr. Maunder gave an account of a paper from the Royal Observatory on the mean areas, &c., of sun-spots in the year 1901, and referred to the apparent connection between the large sun-spot of May 1901 and the disturbed portion of the corona as shown on the eclipse photographs.—Mr. Dyson gave a summary of a paper from the Royal Observatory on the parallax and proper motion of Nova Persei.—Mr. H. C. Plummer partly read a paper on the images formed by a parabolic mirror.—Mr. Whittaker read a paper on periodic orbits in the restricted problem of three bodies, being an extension of the paper read at the January meeting. The problem considered was that of finding the motion of a small planet under the attraction of the sun and a large planet, the latter being supposed to move in a purely circular orbit. Two theorems were communicated in the paper, the first giving a criterion for the existence of periodic orbits and the second being concerned with the value of an integral taken over the orbit.—A note by Mr. Fourcade was read, on Prof. Turner's recent paper on photographic surveying.

Mathematical Society, March 13.—Major P. A. MacMahon, F.R.S., vice-president, and subsequently Lieut.-Col. A. Cunningham, R.E., in the chair.—The Rev. J. Cullen read a paper on the solutions of a system of linear congruences. The object of the paper is to give a graphical process for obtaining the solutions of a system of linear congruences under a given limit; and the scope of the paper consists in establishing and explaining four simple rules to be employed in applications of the process; the process yields new results in the resolution of high numbers, having factors of unknown form, into sums of squares.—Mr. G. H. Hardy communicated a paper on the theory of Cauchy's principal values. This paper is the third of a series concerned with the interpretation, and the use in analysis, of such divergent definite integrals as have in Cauchy's sense a principal value; it deals in particular with the possibility of differentiation and integration under the sign of the principal value, and gives sufficient criteria for the validity of the interchange of order of the limiting operations involved; the theory is illustrated by numerous examples of the calculation of definite integrals by processes which had not previously been proved to be valid.—Mr. R. Hargreaves read a paper on algebraic relations between zonal harmonics of different orders. The coefficients in any sequence equation connecting zonal harmonics are rational functions of the orders of the harmonics, and these functions also are connected by sequence equations; the latter equations are developed systematically.—Dr. F. S. Macaulay made a preliminary communication of some results in the theory of elimination. He showed how to express the resultant of any number of homogeneous equations in any number of variables as a quotient of two determinants.—The following paper was communicated from the chair: Mr. J. Buchanan, on quadrature formulæ. The formulæ are obtained by the use of methods of interpolation based upon central differences.

Entomological Society, March 5.—The Rev. Canon Fowler, president, in the chair.—Mr. L. B. Prout exhibited, on behalf of Mr. J. P. Mutch, *Vanessa* (*Eugonia*) *polychloros*, L., a ♀ bred by Mr. H. Baker from pupa from Stowmarket, Suffolk, the ground-colour much darkened and the black markings somewhat enlarged; *Chrysophanus phlaeas*, L., an aberration (captured in the Isle of Wight, August, 1901) much suffused with dark colour, especially at outer margin and on hindwings, only a very small patch of the red colour remaining at the inner angle of the latter; *Agrotis puta*, Hb., a perfectly halved gynandromorphous example, and *Noctua sobrina*, Gn., an aberrant specimen with white antennæ and a somewhat hoary appearance on the forewings, taken in East Aberdeenshire, August, 1900.—Mr. A. Bacot exhibited a series of *Malacosoma castrensis* and a series of *M. neustria* for comparison with a hybrid brood, resulting from a pairing between a male *neustria* and a female *castrensis*. This was the first time any exhibition of experiments of the kind had been made before the Society by British investigators, though Mr. Merrifield had shown a number of crosses bred by Herr Standfuss. The sexes, as exhibited, were very clearly distinguishable, and there was not much tendency to gynandromorphism, though of sixty or seventy specimens almost every ♀ showed some signs of ♂ coloration.—Mr. O. E. Janson exhibited a pair of *Stephanocrates dohertyi*, Jord., a Goliath beetle discovered by the late W. Doherty in the highlands of British East Africa.—Dr. T. A. Chapman exhibited cocoons of a Limacodid moth from La Plata, with empty pupa-cases of a dipterous parasite of the genus Systropus. The resemblance between the two pupa-cases is, however, not merely of appearance, but functional also. The moth-pupa, *i.e.* the moth itself inside the pupa-case, almost certainly by inflating itself with air, to secure greater size and a stiffened epiderm as a basis of muscular action, exerts an end-to-end pressure within the cocoon, and so forces off a lid. The Systropus breaks off a similar lid, no doubt by similar end-to-end pressure to that exerted by the moth, Diptera having highly developed the habit of inflating themselves with air, at emergence from the pupa. This pupa also has a beak very like that of the Limacodid, but even stronger and sharper.—Mr. J. E. Collin, in further illustration of Dr. Chapman's remarks, exhibited specimens of *Systropus*, sp. ? from Buenos Ayres, parasitic on a Bombycid Lepidopteron (*Limacodes ?*). This, he said, was possibly the same as Dr. Chapman would have reared from his cocoons. The species was apparently undescribed, but most allied to *S. brasiliensis*, Meg.—Prof. E. B. Poulton, F.R.S., read a paper entitled "Five years' observations and experiments (1897–1901) on the bionomics of South African insects, chiefly directed to the investigation of mimicry and warning colours," by Guy A. K. Marshall, with appendices containing descriptions of new species, by W. L. Distant and Colonel C. T. Bingham.—Mr. Malcolm Burr contributed a monograph of the genus *Acrida*, with notes of some allied genera and descriptions of new species —Dr. D. Sharp, F.R.S., contributed three papers by Mr. R. C. L. Perkins, respectively entitled: (*a*) Notes on Hawaiian wasps, with descriptions of new species"; (*b*) "Four new species and a new genus of parasitic Hymenoptera (Ichneumonidæ) from the Hawaiian Islands"; and (*c*) "On the generic characters of Hawaiian Crabronidæ: four new genera characterised."

Geological Society, March 12.—Sir Archibald Geikie, F.R.S., vice-president, in the chair.—The crystalline limestones of Ceylon, by Mr. Ananda K. Coomára-Swámy. The crystalline rocks of Ceylon may be divided into three series: (1) The older gneisses; (2) the crystalline limestones; (3) the granulites (charnockite series)—pyroxene-granulite, leptynite, &c. A local subdivision of this series is the Point de Galle group—wollastonite-scapolite-gneisses, &c. The crystalline limestones of Ceylon are intimately associated with the banded pyroxene- and acid granulites (charnockite series). They form bands with outcrops from a few feet to more than a quarter of a mile in width, interbedded with the granulites. The limestones themselves have a banded structure (foliation) parallel to that of the granulites and to the boundaries. Although the relation of the granulites to the limestones is on the whole intrusive, the two rocks in their present condition are essentially contemporaneous, and seem alike to have consolidated from a molten magma. The calcite occurring in the granulites near the contact has all the appearance of an original mineral. The foliation of the limestones is regarded as a sort of flow-structure, and corresponds with that of the granulites to which it is always parallel. That the foliation does not result from the action of earth-movements on a solid rock is shown by this, that the very minerals whose variable distribution is one of its chief causes have certainly not been affected by deforming earth-movements, nor are they such as to have been produced by these; moreover, in this respect a distinction cannot be made between the limestones and granulites, which would necessarily have suffered alike had they been subjected to deforming strains since the consolidation of the latter. The original nature of the limestones is less evident; they may have been sedimentary or tufaceous, and, if so, subsequently softened and metamorphosed; or possibly *ab initio* truly igneous rocks, and related to the charnockite-magma. Reasons for and against these views are given. The relations between the crystalline limestones and nepheline-syenites of Alnö have suggested to Prof. Högbom that perhaps the limestone may have been a product of the nepheline-syenite magma there. The author feels sure that the crystalline limestones of Ceylon have not arisen by the alteration of the basic lime-silicates of the pyroxene-granulites.—On Proterozoic gasteropoda which have been referred to Murchisonia and Pleurotomaria, with descriptions of new subgenera and species, by Miss

Jane Donald. Many of the Palæozoic shells referred to Murchisonia do not agree with the type, and there are at least two separate groups distinguished by the outer lip. The typical group has a slit, the other merely a sinus. From the material at present available, in the British Isles as well as in America and the Baltic provinces, elongated forms with a sinus precede those with a slit. So far, no light is thrown on the question as to whether Murchisonia and Pleurotomaria were derived from the same stock, nor has the author yet met with any specimens showing a transition from sinus to slit.

PARIS.

Academy of Sciences, March 17.—M. Bouquet de la Grye in the chair.—Some remarks on the periods of double integrals and the transformation of algebraic surfaces, by M. Emile Picard.—Studies on vegetable earth, by M. Th Schlœsing. The earth is separated by a process of levigation into fractions, which are analysed separately. The most striking fact obtained by this method of working is the rapid change in the proportions of iron and phosphoric acid in the fractions. The ratio of iron to phosphorus, however, remained practically constant.—On the culture of the fodder beet, by M. P. P. Dehérain. The method of cultivation of the beet, which aims only at producing roots of the largest size, is faulty, as analyses of such roots show that they contain an undue amount of water and nitrates. By planting out so that smaller beets are obtained, it was found that although the gross weight per hectare was somewhat less in the latter case, the weight of dry material was greater and the loss of nitrates was reduced.—M. Yermoloff was elected a correspondant in the Section of Rural Economy in the place of the late Sir J. B. Lawes.—On regular groups of finite order, by M. Léon Autonne.—On the theory of algebraic functions of finite order, by M. Beppo Levi.—On the conservation of refractive energy in mixtures of alcohol and water, by M. A. Leduc. The refractive indices of mixtures of alcohol and water can be calculated from the refractive indices of the two constituents within the limits of experimental error, allowance being made for the contraction which takes place on mixing the two liquids.—On the mobility of the ions in gases, by M. P. Langevin.—Research on a unit for measuring the force of penetration of the X-rays and for their quantity, by M. G. Contremoulins. The principle adopted for these measurements is the comparison of the intensity of illumination of a fluorescent platinocyanide screen with a screen artificially illuminated with a light of known intensity.—The heat of reaction between bodies in the solid and gaseous state, by M. Ponsot.—The heats of solution of solid and liquid ammonia taken at about $-75°$ C., and on the latent heat of fusion of solid ammonia, by M. G. Massol. The method adopted was to dissolve first liquid ammonia and then solid ammonia, both as near $-75°$ C. as possible, in water in a calorimeter; the latent heat of fusion was thus obtained as the difference between these two results. The value thus found for the latent heat of fusion for a gram-molecule of solid ammonia was -1.838, approximating to that of water, -1.43.—The volumetric estimation of thallium, by M. V. Thomas. The author has modified the iodometric method of Feit, in such a manner as to avoid the conversion into the sulphate. Test analyses are given showing the accuracy of the method as modified.—Acid and basic sulphates of neodidymium and praseodidymium, by M. Camille Matignon. Four new sulphates are indicated, their properties determined, and their thermochemical relations examined.—A method for the alkalimetric estimation of disodium-methylarsenate or arrhenal, by M. A. Astruc. The method suggested is based on the fact that in the presence of rosolic acid one molecule of this substance requires one molecule of a monobasic acid for neutralisation.—On some derivatives of arabinose, by M. G. Chavanne. The exact conditions are given for the production of a pure substance in the interaction of arabinose with acetyl chloride and bromide. The preparation and properties of the phenylhydrazone of arabinose are also described.—On the supposed binaphthalene-glycol, by M. R. Fosse. It is shown that the body described as binaphthalene-glycol is in reality dinaphthoxanthydrol, and that the derivatives of the supposed glycol are similarly constituted.—On the pseudo-acids, by M. P. Th. Muller. For a true acid the difference of the molecular refractions of the acid and its sodium salt should be equal to the difference of the molecular refractions of sodium hydrate and water, and for a large number of acids of the order of acetic this has been found to be the case, the value of this constant difference being about 1.55. Any marked variation from this value would indicate that the constitution of the acid was different from its neutral salt. This the author has found to be the case for a certain number of isonitroso-compounds of the fatty series.—On the classification of the Cercomonadines, by M. Louis Léger.—The use of organic arsenic and phosphorus compounds in the treatment of tuberculosis, by M. A. Mouneyrat. Sodium methylarsenate taken alone has no effect in preventing the excessive elimination of phosphorus in tuberculosis. But by the administration of this salt, together with an easily assimilable phosphorus compound, such as nucleinic acid, the desired result was obtained. A marked improvement was noticed in less than a month, with gain in weight, increase in appetite, disappearance of the nocturnal sweats, and of fever. At the end of a month or six weeks the sputum became normal, losing its purulent character and, in the majority of cases, with the disappearance of the tubercle bacillus.—The action of temperature on the mineral absorption in etiolated plants, by M. G. André. It was found that the quantity of ash in 100 parts of the dried material is always greater in the normal plant than in the plant etiolated at 15° C.; the reverse was the case in an etiolated plant growing at 30° C., the difference being entirely represented by silica.—On the assimilation of carbon by a green algæ, by M. P. G. Charpentier.—A bacteriological study of the *massif* of Mont Blanc, by M. Jean Binot. The number of germs in the air at the summit of Mont Blanc is extremely small, varying between four and eleven per cubic metre, and increases as the valley is approached. The ice, snow and water on the mountain were made the subject of a separate study. A virulent pyocyanic bacillus was isolated from the ice at the summit, and an exceedingly pure water taken near the Montanvert showed twelve colonies of a virulent *Bacterium coli* per cc.—Experimental researches on the mental life of a xiphopage, by MM. N. Vaschide and H. Piéron.

ELASTICITY FOR ENGINEERS.

Résistance des Matériaux et Éléments de la Théorie mathématique de l'Élasticité. Par Aug. Föppl. Traduit par E. Hahn. Pp. 490. (Paris: Gauthier-Villars, 1901.) Price fr. 15.

DISCUSSIONS as to the amount of "learning of mathematics" necessary for the engineer have not been confined to this country, but have, as we learn from the preface, been keenly carried on in Germany. There appears to be a desire in some quarters to sacrifice mathematical teaching to laboratory work, on the ground of the great increase in the number of hours necessary for the latter in consequence of modern developments of electro-technics; and some writers have attempted to bring forward as an argument the rarity of the occasions on which mathematics is required by the engineer, and the large amount of time that is required to obtain a knowledge of that subject.

Prof. Föppl takes an entirely different view. While admitting that no advantage is gained by the study of purely speculative branches of mathematics, he is directly opposed to any tendency to lower the general level of mathematical knowledge of our future engineers. He lays stress on the value of mathematical training in enabling the practical man to *draw correct conclusions* on the numerous questions on which he is required to pronounce judgment, even where actual calculations are not required.

This is a view which ought to be more keenly appreciated among practical men than has been the case hitherto, and we should like to see put forward an entirely opposite suggestion to that which has apparently found favour in some circles in Germany, namely that *more* attention should be given to mathematics in the training of engineers *even* at the expense of laboratory work. It is sufficient to take up any volume of engineering transactions to find the "practical" man "plunging" into pages and pages of elaborate formulæ involving "shines and coshes," and in the end either getting no result of interest, or obtaining a simple deduction of some principle well known to every mathematician, but which the writer of the paper puts forward as if it were a new physical law. On the other hand, the engineer who has an intimate knowledge of pure and applied mathematics will know, for example, what partial differential equations are involved in the solution of any problem placed before him, and even if he knows that it is impossible to solve these for the particular type of boundary with which he has to deal, he will form a complete mental picture of the machinery underlying the system he is investigating; he will mentally classify the known and unknown quantities involved in the problem, and will see at a glance the right lines on which to determine the unknown quantities experimentally, instead of spending hours in floundering through formulæ or wasting money over superfluous experiments.

The theory of elasticity probably enters into the work of the engineer more intimately than any other branch of applied mathematics, and, at the same time, there are few subjects so difficult to present to the learner in a form that will furnish him with a definite mental picture of the phenomena concerned. So far as we are aware, no one has, as yet, ever attempted to construct diagrams of the deflections of a rectangular sheet of steel plating by dotting it over with microscopists' cover-glasses, silvered on the back, allowing these to reflect light from a source on to a screen and observing or photographing the displacements of the bright spots when one side of the plate is submitted to pressure or a weight is applied at any point of its surface; yet this would not be difficult to do, and would certainly give interesting results.

The present work is the French translation of a book written by Prof. Föppl expressly for the purpose of giving engineers an insight into the mathematical theory of elasticity. It commences with a chapter on the analysis of stresses, which we regret to see entitled "Forces intérieures ou actions moléculaires." When will writers adopt some consistency in their use of the words *molecule* and *molecular?* In text-books on hydrodynamics, the term *molecular rotation* is often found applied to a quantity which by no means represents the rotation of the actual molecules of the fluid, but is merely the curl of the velocity. Thus it follows that the "molecular rotation" of Basset and other text-book writers vanishes when a fluid is moving irrotationally, while the kinetic theory of gases tells us that in a mass of gas *at rest* the molecules are in rapid rotation, the kinetic energy of the true molecular rotation bearing a determinate ratio to that of molecular translation, except probably in the case of a monatomic gas. Similarly M. Föppl takes no account of the molecular structure of the body, there is no reference to Boscovich's or any other hypothesis, and his "molecular" actions, so-called, are nothing more or less than the ordinary stresses in the element $dx\ dy\ dz$. Seeing that $dx\ dy\ dz$ is called an element, why not consistently use the term "elemental" or "elementary" for such actions? In the next chapter, which deals with analysis of *strain* as opposed to stress, this is done, the nomenclature "déformations élémentaires" being adopted. This chapter contains discussions on the elastic limits, Woehler's experiments and diagrams of the relations between stress and strain beyond the limits of Hooke's law. The third chapter is devoted to flexure of beams, and it includes digressions on moments of inertia and the method of finding them with a planimeter. Of graphical interest is the diagram showing the enveloping curves of the lines of stress (p. 120). The next chapter deals with the potential energy of deformation, and includes Castigliano's interesting theorems and Maxwell's reciprocal property.

Chapter v. deals with curved beams or prisms, and the next chapter with the problem (prisms resting on a compressible base) presented by the yielding of railway metals under the weight of a train. This is followed by a chapter on the plane plate, after which come thin and thick shells. The ninth chapter deals with the torsion problem. The solution for a rectangular beam is, however, wrong. The author finds stress components represented by algebraic expressions of the third degree, and shows that these satisfy the stress-equations, but he omits to show that these expressions are compatible with the strain-equations—professedly in order to obtain

as simple a result as possible, even if approximate, but really because his is not the correct solution of a problem, that obtained by Saint Venant's method involving series of transcendental functions. We miss the well-known equilateral triangle and the algebraic solutions representing sections approximately square. Chapter x. deals with the collapse (*flambement*) of beams under end thrust or torsion.

"The elements of the mathematical theory of elasticity" is the title of the last chapter. In it the differential equations of elasticity are expressed in terms of the displacements, and the applications include wave-propagation, Saint Venant's torsion problem (still without reference to the rectangle or equilateral triangle), Boussinesq's and Hertz's theorems.

A special feature of the book is the collection of examples at the end of each chapter. These, of which the solutions are given, are, as examples should be, mostly straightforward applications, frequently numerical, of the bookwork, and though some of them are necessarily rather long, none of them are without some practical interest. It is very likely that many a mathematician brought up on tripos riders might find the numerical calculations puzzling at first, but is it not essential to understanding a theory properly that it should be tested by numerical examples and not merely by "neat analytical results"? Another feature is the synopsis of formulæ at the end of the book.

This is not exactly the book which a mathematician would use to learn elasticity from by preference, but then it was not written for mathematicians. In endeavouring to present the theory of elasticity in the most practical aspect possible so as to bring it within the range of engineering students, the author appears to have achieved his object with remarkable success, or in the conventional words of the reviewer, "this book is admirably adapted to the requirements of the class of readers for whom it is specially written."

DETERMINATIVE BACTERIOLOGY.

A Manual of Determinative Bacteriology. By Frederick D. Chester. Pp. vi + 401. (New York: The Macmillan Company, 1901; London: Macmillan and Co., Ltd.) Price 10s. 6d. net.

ALL branches of science in the early stages of their development suffer from the want of a uniform nomenclature. But it is in the biological sciences, especially zoology and botany, that the greatest confusion has prevailed, more particularly in the naming of the multitudinous forms of animal and plant life. Thanks, however, to the codes of rules drawn up at various conferences, and more or less universally accepted, the systematic nomenclature of zoology and botany has become much more uniform and simple, while these branches both possess a recognised terminology for descriptive purposes.

It is otherwise with bacteriology. This science, though primarily a branch of botany, has been mainly developed by those who could not claim to be trained botanists, and the bacteria have been studied and classified with little reference to the relations existing among themselves and to allied forms; hence the nomenclature, both systematic and escriptive, is in a chaotic state. Moreover, descriptions of new forms are continually appearing in a number of journals, so that it is extremely difficult without an enormous expenditure of time to discover whether a form has previously been described or no, as hitherto there has been no catalogue of species available. It is with a view to purge bacteriology of some of these reproaches that the present work has been compiled. The author modestly states in the preface that he "does not claim that the system of arrangement is perfect. . . . The present tables serve, therefore, only for purposes of identification and not necessarily for those of classification." The opening chapter is devoted to an account of the morphology and biology of the bacteria; in the second a genuine attempt is made to devise a system of terminology for descriptive purposes. The various forms of growths, of colonies, &c., receive appropriate names, so that what was formerly a long description may be condensed into a few words. For instance, the gelatin stab culture of anthrax is "an arborescent growth becoming a crateriform to saccate liquefaction," and the agar colonies of the same organism are simply "floccose." The preparation of standard nutrient media is then described, a reaction of + 0·5 being preferred to that of + 1·5 adopted by the Committee of the American Public Health Association. Some staining methods are next briefly mentioned, and a few pages are devoted to a study of the chemical functions of bacteria, a table of chemical separations, and a scheme for the study of bacteria.

In chapter iii. the classification of the bacteria is dealt with, that adopted being on the basis of the one described by Migula in his "System der Bakterien," and the various species are tabulated at length and upon a definite scheme. This portion of the book occupies more than 300 pages and must have entailed considerable labour in its compilation. The cultural and other characters of each organism are described upon a consistent plan, while the various species are divided up into small groups by certain prominent characteristics, such as chromogenic, liquefying, Gram-staining and other properties. By this subdivision, and the synopsis of characters given before each group, it is possible, as the author points out, to place a culture in the hands of a student and for him to determine the species. Those who are acquainted with the older works of Eisenberg, Lustig, &c., will accord a hearty welcome to these tables. The classification, as stated before, is that of Migula, but the nomenclature of species has been made to accord with the rules of botanical nomenclature, with a rigid insistence upon binomial names and upon the rule of priority. At the same time, the synonymy of, and earliest reference to, each species is given. This is no doubt a great advance, though perhaps inconvenient at first, as it involves the renaming of a number of familiar species, sometimes with far less appropriate names than they have at present. For example, the bacillus of mouse septicæmia was conveniently termed the *Bacillus murisepticus* by Flügge in 1886, but a year previously Trevisan had named it the *Bacterium insidiosum*, and therefore "*insidiosus*," by the rule of priority, must stand as the specific name. Curiously enough, having discussed this very organism as an example of the rule of priority at length at p. 48, when it comes to the actual description of it (p. 353) the author tabulates it as *Mycobacterium murisepticum* in-

stead of "*insidiosum*," as, from his own showing, it should be. Similarly, the bacillus of hog cholera, the *B. suipestifer*, Kruse, becomes the *B. Salmoni*; the organism of chicken cholera the *B. cholerae*; Koch's comma bacillus of cholera *Microspira comma*, &c.

In a work which as a whole is so excellent, it would be invidious to criticise minor points, and the following remarks should therefore be regarded as suggestions for amendment in a future edition.

The description of the *Bacillus enteritidis*, Gärtner, is too brief, and this organism does not ferment lactose. All peritrichic forms are indicated by a "B" in heavy type. Those which are presumably so, but about which there is no definite information, are designated by a "B" in lighter type; the distinction between the two letters should be made more marked. The *B. Welchii* and *B. emphysematosum* (p. 183) are, according to Welch, identical. In places the terminology needs revision, *e.g.* *M. eczemae* (p. 86) and *M. epidermis* (p. 62). The reviewer has searched in vain for any mention of the *Micrococcus melitensis*.

While the index is a very full one, it might be yet more complete with advantage—for example, in all cases both the ordinary name and the one adopted should be given, but this is not done. Anyone searching for the *M. agilis* would not find it unless he knew that the organism was flagellated and belonged to the genus Planococcus. There is no reason why "Bacterium" should be indexed before "Bacillus." The *B. aërogenes capsulatus* is wrongly indexed (p. 269, instead of p. 183). The work concludes with a glossary of terms and a short bibliography. As regards the latter, one reference reads "Trevisan-de-Toni, &c."; it should be "Trevisan *and* de Toni in, &c." Moreover, another work by Trevisan, "Gen. e spec. delle Batteriaceæ" (1889), although frequently alluded to in the text, is not mentioned in the bibliography.

R. T. HEWLETT.

STRATIGRAPHICAL GEOLOGY.

The Student's Handbook of Stratigraphical Geology. By A. J. Jukes-Browne, B.A., F.G.S. Pp. xii + 589. (London: Edward Stanford, 1902.) Price 12*s*. net.

AS stated in the author's preface, "this volume is based upon the 'Student's Handbook of Historical Geology' published by Messrs. G. Bell and Sons, and may be regarded as a second edition of that book." It has been entirely rewritten, however, and brought up to date; moreover, the alterations and additions are so numerous and important that to describe it without qualification merely as a second edition of that work is, we think, to give a wrong impression of its increased merits.

The former book, which was published in 1886, was in most respects an excellent work and contained a surprising amount of information; but, in our opinion, it had a serious defect. It was somewhat lacking in interest, dry, and not very readable. Fortunately for the student, this fault, which it is very difficult, often impossible, to avoid when, as in this case, the information to be imparted consists in the main of the statement of a host of details, has in the present volume been largely remedied; and the author is to be congratulated upon the manner in which, while greatly augmenting the number of recorded facts, he has succeeded in maintaining the general interest of his subject.

Of the eighteen chapters which comprise the text of the volume, the first four deal with the principles involved in the science of stratigraphy. They follow the same general plan as was previously adopted. The fifth, however, is quite an innovation. It gives information to the student as to the principal works on general stratigraphy which are available in this country, and as to the facilities which exist for ascertaining what has been published, in the way of maps and special treatises, concerning the stratigraphical geology of any district in the British Isles of which he may wish to acquire a deeper knowledge. It should prove especially useful to students who are self-taught.

The remaining chapters are devoted to the study of the several geological systems, which are taken, as before, in the ascending order. The nomenclature adopted for the systems is simple and satisfactory. The substitution of the terms Palæogene and Neogene, originally suggested by Hœrnes for the Tertiary systems and now widely employed on the continent, in place of the terms Hantonian and Icenian used in the first edition, is, we think, an improvement in terminology. The chapters dealing with the Palæozoic systems have been very considerably expanded, with the result that these systems now receive a fairer share of attention than was the case in the first edition.

The author has adopted a capital plan of placing the literature-references at the end of each chapter, where, with the addition of such others as are necessary to make the list tolerably complete, they constitute a most useful bibliographical index of the subject dealt with in the chapter.

The main bulk of the book treats of British stratigraphy. Such accounts as are given of foreign rock-groups are comparatively short, and, except in a few special cases, are confined to those of the European continent. This, to some extent, limits the use and value of the book; but to us it seems that the author has done well to make his description of foreign strata quite subordinate to that of beds at home which every student has the opportunity of seeing and examining in the field for himself. In order to have included a satisfactory treatment both of British and foreign stratigraphy it would have been necessary to increase the size of the volume to such an extent that its cost would be prohibitive to most of those for whom it is especially written.

One of the greatest improvements in the book in its new form is the addition of a number of sketch-maps illustrating the geology of many of the more specially interesting districts in England and Wales. These, which are in part derived from previous publications and in part have been prepared for the work, from the maps of the Geological Survey, are clearly and effectively drawn, and greatly facilitate a ready comprehension of the text. The author's suggestion that the student should tint them with suitable washes of colour is a good one; the exercise intelligently carried out, besides enhancing the value of the diagrams, should also serve to impress the geology of each district more permanently upon his mind.

The number of explanatory geological sections has been considerably increased, and the same is true of the figures of fossils. The volume is, indeed, admirably illustrated. It is an important and welcome addition to the list of English treatises which are especially designed for the use of the student of stratigraphical geology, and one which we can most confidently recommend, not only to students, but to all who desire a trustworthy representation of the present state of our knowledge of British stratigraphy.

OUR BOOK SHELF.

Birds' Nests, an Introduction to the Science of Caliology By Charles Dixon. Pp. xiv + 285; i illustrated (London: G. Richards.) Price 6*s.* net.

IF we may judge from a statement on p. 7, Mr. Dixon is of opinion that stone-throwing is a proper and suitable practice for the tenants of glass houses. For since he classes Darwin as a "compiler," he can scarcely have the presumption to exclude himself from the same category! As a matter of fact, Mr. Dixon's works are to a great extent compilations from the writings or observations of others, and the present volume appears to be no exception to the rule.

That popular works of the class of those for which Mr. Dixon is responsible must almost necessarily contain a large percentage of copied matter we are fully prepared to admit, but when the author of such works sees fit to refer in contemptuous terms to one of the master minds of the last century he must not be surprised if critics treat his own productions and methods with scant courtesy.

In the volume before us, Mr. Dixon claims to have opened up a practically new branch of ornithology, which he designates, very unnecessarily, as "caliology." He further states that no work has been entirely devoted to this subject for the last seventy years. In this it may be taken for granted that he is correct, although it would be a mistake to suppose that other writers have not devoted a considerable amount of attention to the subject. Indeed this is evident from the work itself, in which the author quotes the views of Dr. A. R. Wallace, Dr. E. Goeldi and other eminent zoologists. Mr. Dixon has the knack of putting what he has to tell in an agreeable and attractive manner before the public, and had he not gone out of his way to cast a slur on the reputation of a great man we should have been more inclined to bestow a modicum of praise on his efforts than we feel justified in doing as matters now stand.

The plan of the work is to describe the nest-building of birds in a progressive manner, commencing with those species the nests of which are of the simplest type (or rather with those which make no nests at all), and gradually passing on to those, such as the tailor-birds and hang-nests, which construct nurseries of the most elaborate type. Mr. Dixon is one of those who believe that the nest-building instinct is not inherited and that birds learn to build by practice and instruction. He considers this belief to be strengthened by the case of a nest (which he figures) built by a pair of chaffinches taken to New Zealand before their first nesting season. The nest built by them in the antipodes is of a very abnormal type; but is it certain that this may not be accounted for by difference of environment and material? Another plate, in which the bird is depicted in a very remarkable posture, shows the eggs of a greenshank in the deserted nest of a fieldfare. We may say in conclusion that those who have never previously studied birds' nests with attention will find much to interest them in Mr. Dixon's latest volume.

R. L.

Lancashire Sea-Fisheries Memoir. No. 2, *Fish and Fisheries of the Irish Sea.* By W. A. Herdman, D.Sc., F.R.S., and Robert A. Dawson. Pp. 98. (Liverpool: Philip.) Price 5*s.* net.

IN the second of the Lancashire Sea-Fisheries Memoirs, Prof. Herdman and Mr. Dawson summarise, for the use more especially of the members of the Lancashire and Western Sea-Fisheries District Committee to whom the volume is dedicated, the more important results bearing upon practical fishery questions which have been obtained from the scientific researches carried on during recent years in the Irish Sea. The information given is for the most part not new to the scientific student, as it has already been made known through the various reports of the Liverpool Biological Society.

The work commences with a useful account by Prof. Herdman of the physical and biological conditions which are found in the Irish Sea, more especially in that part of it which lies between the Isle of Man and the Lancashire Coast. This account includes some interesting information, supplied by Mr. Clement Reid, on the geological features of the bottom deposits obtained from different parts of the area under consideration.

After a brief description of the invertebrate fauna, a complete list of the fishes of the district is given, with details of the geographical and local distribution of each species. It is to be regretted that more information as to the habits and life-histories of the various fishes is not supplied in this portion of the work, as such information would have rendered it both more interesting and more useful to those for whom it is intended.

The memoir concludes with a chapter by Mr. Dawson on the constitution and work of the Lancashire and Western Sea-Fisheries Committee and two appendices, one containing the bye-laws of the Committee and the other some detailed results of various experimental hauls of the trawl.

Plant Structures. By John M. Coulter, A.M., Ph.D. Pp. vii + 348. (London: Hirschfeld Brothers, Ltd., 1901.) Price 6*s.* net.

FORMER books by the professor of botany in the University of Chicago have been characterised by a concise and rational elucidation of the subjects treated, and this applies also to the book under discussion. In "Plant Relations," a first book on botany, Prof. Coulter dealt mainly with ecological factors. "Plant Structures" gives a brief outline of the various great groups of the plant kingdom. The life-histories of common or important types are used to illustrate the gradual transition from the lowest algal plants to the complex, highly modified group of spermaphyta, and also to introduce the student to the widely varying structures and methods of reproduction which obtain among plants. The types chosen are, for the most part, similar to those found in other elementary text-books; a new ascomycetous type is furnished by *Microsphaera*, a mildew which occurs on lilac leaves. In addition, many other interesting examples are quoted and, to a great extent, illustrated; in fact, there is an almost superabundant wealth of illustration.

It cannot be said that the author has struck any original vein, but the strength of the book lies in clear and sound representation of facts, and in logical sequence of argument; also, where it is appropriate, the result of recent work has been embodied, as, for instance, the occurrence of sperms in the Cycads, and chalazogamic fertilisation in the Dicotyledons, for which original illustrations are given. The author is especially happy in his treatment of the Angiosperms as he traces the various evolutionary series of floral modifications. There are two points in which there will not be general agreement with the author; the term "spore" is not confined to sexual reproduction, but the result of fusion of ovum and sperm is also defined as a spore; again, how can the spelling of *Edogonium* be made to accord with its derivation?

LETTERS TO THE EDITOR.

Magic Squares of the Fifth Order.

IN the interesting discourse reproduced in your issue of March 13 (p. 447), there is a statement that the number of magic squares of order 5 exceeds 60,000. Major MacMahon informs me that he gave these figures on the authority of Rouse Ball's "Mathematical Recreations." The statement is not wrong, but viewed as a minimum limit it may be largely exceeded. I have recently investigated the total number of squares of this order, which have the additional property that the nine numbers in the heart of the square also form a magic—the well-known "bordered squares." Fig. 1 is an example. The square itself is magic in rows, columns and diagonals, and the nine numbers in the central square show like properties.

It is easy to see (1) that the numbers in the central square must consist of three arithmetical progressions with a like common difference; (2) that the first terms of each progression must also be in arithmetical progression; and (3) that the mean number (13) must always occupy the central cell. Hence it follows that (excluding the central number) the eight numbers in the heart must consist of four pairs of complementary numbers (*i.e.*, pairs whose sum is 26, or twice the mean), and also that the two smallest numbers being known, then all the others are known. If, for example, the two lowest numbers in the heart are a, $a+k$, then the nine numbers in the centre, taken in numerical order, must be a, $a+k$, $a+2k$; $13-k$, 13, $13+k$; $26-2k-a$, $26-k-a$, $26-a$. It is now easy to determine in how many ways we may choose the nine numbers for

the centre on the usual assumption that we are restricted to the first 25 natural numbers without repetition or omission. The total is 26, as shown in the first column of the table below, where the figures in brackets denote the two lowest numbers in the heart.

Type.	Number of subtypes.	Type.	Number of subtypes.
A. (1, 2) ...	... 28	N. (4, 5) ...	... 30
B. (1, 3) ...	... 31	O. (4, 6) ...	... 23
C. (1, 4) ...	... 18	P. (4, 8) ...	... 30
D. (1, 6) ...	... 21	Q. (5, 6) ...	... 16
E. (2, 3) ...	... 30	R. (5, 7) ...	... 20
F. (2, 4) ...	... 30	S. (5, 8) ...	... 20
G. (2, 5) ...	... 26	T. (6, 7) ...	... 19
H. (2, 6) ...	... 29	U. (6, 8) ...	... 18
I. (2, 7) ...	.. 23	V. (6, 9) ...	... 28
J. (3, 4) ...	... 23	W. (7, 8) ...	... 19
K. (3, 5) ...	... 23	X. (8, 9) ...	... 29
L. (3, 6) ...	... 13	Y. (8, 10) ...	... 18
M. (3, 7) ...	... 27	Z. (9, 10) ...	... 10
TOTAL ...		...	... 602

These we may call the 26 main types of bordered squares of the fifth order. The 16 remaining numbers have evidently to be arranged in the four borders in such a way that complementary pairs are opposed at the opposite ends of rows, columns, or diagonals, with the additional condition that the four borders must each sum 65. Now when we deal a pair of complementary numbers into the top and bottom rows, we clearly give to those rows a difference equal to the difference of the complementary pair. If we call this a "complementary difference," then the numbers in the two rows must be so related that the sum of two complementary differences must equal the sum of the other three, and a similar relation must hold between the two lateral borders. Suppose we are dealing with type L. (3, 6). The numbers for the centre are 3, 6, 9; 10, 13, 16; 17, 20, 23. If now we arrange the remaining numbers in two columns, with complementaries adjacent, and form a third column of half differences, we have:—

		Half Difference.
1	25	12
2	24	11
4	22	9
5	21	8
7	19	6
8	18	5
11	15	2
12	14	1

It is then necessary to form two equations from the column of half-differences of the form $a+b=c+d+e$, and so related that two and only two numbers shall be common to both equations, and that these two shall be on opposite sides of the equality sign in one equation, and on the same side in the other. In the case of type L. we can do this in thirteen different ways, as shown below, the italicised figures denoting the corner pairs:—

$$\left.\begin{aligned}12+11&=9+\mathit{8}+\mathit{6}\\ \mathit{6}+5&=\mathit{8}+2+1\end{aligned}\right\}a. \qquad \left.\begin{aligned}12+\mathit{8}&=9+\mathit{6}+5\\ \mathit{8}+\mathit{6}&=11+2+1\end{aligned}\right\}b.$$

$$\left.\begin{aligned}12+\mathit{6}&=9+\mathit{8}+1\\ 11+5&=\mathit{8}+\mathit{6}+2\end{aligned}\right\}c. \qquad \left.\begin{aligned}12+6&=\mathit{9}+8+\mathit{1}\\ \mathit{9}+5&=11+2+\mathit{1}\end{aligned}\right\}d.$$

$$\left.\begin{aligned}\mathit{12}+5&=9+6+2\\ 11+8&=\mathit{12}+\mathit{6}+1\end{aligned}\right\}e. \qquad \left.\begin{aligned}12+5&=9+\mathit{6}+\mathit{2}\\ 8+\mathit{6}&=11+\mathit{2}+1\end{aligned}\right\}f.$$

$$\left.\begin{aligned}12+2&=8+\mathit{5}+\mathit{1}\\ 11+\mathit{5}&=9+6+\mathit{1}\end{aligned}\right\}g. \qquad \left.\begin{aligned}12+\mathit{1}&=6+\mathit{5}+2\\ 9+8&=11+\mathit{5}+\mathit{1}\end{aligned}\right\}h.$$

$$\left.\begin{aligned}\mathit{11}+\mathit{9}&=12+6+2\\ \mathit{9}+8&=\mathit{11}+5+1\end{aligned}\right\}i. \qquad \left.\begin{aligned}11+9&=12+\mathit{6}+\mathit{2}\\ \mathit{6}+5&=8+\mathit{2}+1\end{aligned}\right\}j.$$

$$\left.\begin{aligned}\mathit{11}+8&=12+6+\mathit{1}\\ 9+5&=\mathit{11}+2+\mathit{1}\end{aligned}\right\}k. \qquad \left.\begin{aligned}\mathit{11}+8&=12+\mathit{5}+2\\ \mathit{11}+\mathit{5}&=9+6+1\end{aligned}\right\}l.$$

$$\left.\begin{aligned}11+5&=8+\mathit{6}+\mathit{2}\\ 9+\mathit{6}&=12+\mathit{2}+1\end{aligned}\right\}m.$$

Each of these 13 pairs yield a subtype under type L. For example, take the first pair. The first equation tells us that the greater of the two pairs of numbers whose half-differences are 12 and 11 can be associated in one border with the lesser of the three pairs whose half-differences are 9, 8 and 6, the complements, of course, being opposed in the opposite border. The other equation gives similar information regarding the other two opposed borders. The centre can be arranged at once by following the order of the ordinary magic of the third degree. The result is shown in Fig. 2.

The table above gives the number of subtypes for each main type, the total being 602. The result has been verified by another worker independently.

It is now easy to calculate how many bordered magics of the fifth order exist. The centre for a given subtype we know can be arranged in one way only if reversions and reflections are *not* reckoned as different; in eight ways if they are so reckoned. Consider the top row in any one of the 602 subtypes. For the left-hand corner we have four choices, for the next cell six, and for the third cell two. This leaves three choices for the second cell of the left-hand border and two for the third. The numbers in all the remaining border cells are now known. There are, therefore, $4\times 6\times 2\times 3\times 2=288$ ways of arranging the borders for each sub-type. The total number of squares is thus $602\times 288\times 8$ if reversions and reflections are reckoned as different; $602\times 288=173,376$ if they are not so reckoned.

When we bear in mind that this is the number of magics of a restricted type, it is clear that the number of magics of the fifth order must largely exceed this total; indeed, everything suggests that the totality of magics of the fifth order is more than twice as great as the above result.

Haywards Heath, March 15.

Rotation of a Lamina Falling in Air.

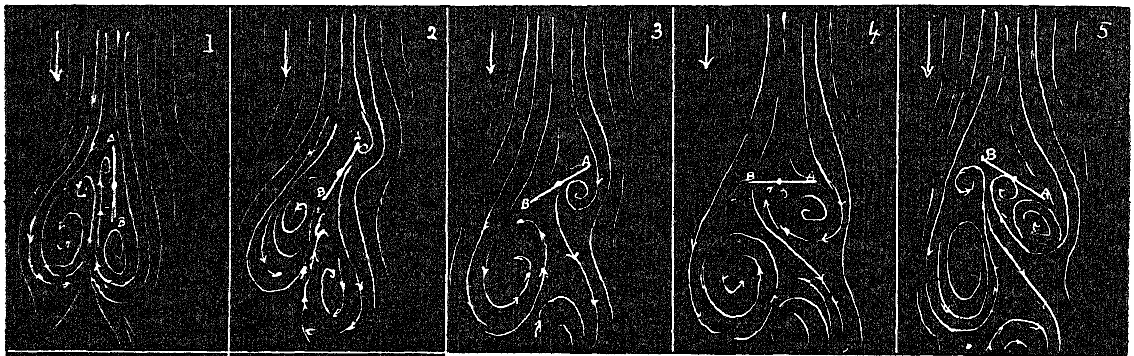
IN your issue of March 20, Dr. Johnstone Stoney, in reference to the behaviour of ice spiculæ in the clouds, instances the spinning of a card when dropped through the air.

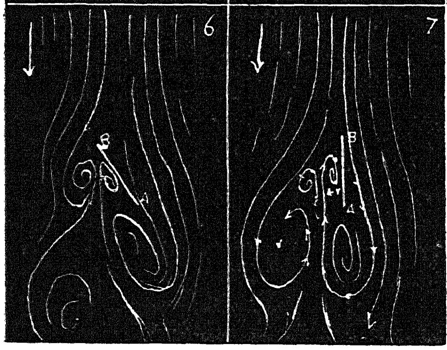
I think Lord Rayleigh was the first person to point out how curious this phenomenon is and to show that the axis of a spinning lamina might be held between bearings without affecting the result. Also that a lamina so held and placed in a draught was equally ready to spin in either direction, thus precluding the idea that the rotation might be due to some want of symmetry in the lamina itself.

A few years ago I made some experiments on the rotation of laminæ in air currents.

The laminæ were mounted in bearings as frictionless as I could make them, and the experiment consisted (*a*) in measuring the speed of the air and the angular rotation of the lamina, (*b*) in mapping the flow of the air past the lamina. This was done by the use of smoke and intermittent illumination.

It would take too long to describe the apparatus in detail, but some of the results may be of sufficient interest for publication.





Sketches of the position ot the eddiesf ormed in the neighbourhood of a rotating lamina, A B.

Thus, the angular velocity of the lamina was found to be (through a considerable range of air speed, v, and breadth of lamina, b) = constant $\times \frac{v}{b}$.

There is a limit, however, to the smallness of the lamina which will revolve (*e.g.* small laminæ of gold-leaf a tenth of an inch long and two or three hundredths broad do not revolve, but oscillate as they fall).

The cause of the rotation depends on the way in which the eddies are formed on the downstream side of the lamina.

The changes which occur, in the eddy making, during half a revolution are shown in the accompanying sketches.

From these it will be seen that the spin causes the air to flow unsymmetrically with regard to the axis of the lamina, and that there will be, on the whole, a transverse force on the axis tending to press it in the direction of rotation of the leading edge.

It can be seen also that *before* the lamina reaches the positions 1 or 7, there will be a couple acting on it tending to accelerate the rotation, and that the couple will certainly be positive from position 1 to 3. It may be negative from between positions 3 and 4 to 6; but at any rate for more than half the total time the rotation is being accelerated.

To calculate the magnitude of the couple *a priori* is, I believe, beyond the power of mathematical analysis at present.

The experiments just alluded to were made with light rectangular laminæ, but these conditions are not essential—pennies spin very nicely when dropped from a great height.

I have not succeeded in making a lamina spin in a current of water, probably because the densities of the fluid and solid are not sufficiently different, but if a flywheel were fixed on the axis of the lamina, so as to be out of the water, and thus increase the moment of inertia of the turning body without altering the fluid friction, &c., rotation might perhaps be obtained in this case also.

March 22.

Mathematics and Science at Cambridge.

To those who have at heart the advancement of scientific knowledge in Great Britain it is impossible but to acknowledge that the country owes a profound debt of gratitude to the University of Cambridge. During the dark ages of education her colleges formed the stronghold of modern culture; and the principle was there maintained that to the students of dead languages, however paramount they might be without her walls, within them no more than equal rights should be conceded. This involved a contest in which the principals were the mathematicians and classics, and the terms of peace a system of specialisation coupled with a certain test examination, an inquisitorial farce known as the Little-Go. This system, adopted doubtless in order to obviate the difficulty of forming a combined curriculum of studies which appealed to totally dissimilar tastes, has since been so widely extended in its application as to divorce subjects which are germane in character and naturally adapted for a close alliance. The climax is reached in the ever-growing barrier which separates mathematics from natural science, and which is year by year made more impassable by the examinations for entrance scholarships. These are of high value; and without this aid from the funds which the college authorities hold in trust for educational purposes many a brilliant man would be unable to consummate his work at school by a university career. It is, therefore, necessary that school curricula should be arranged in strict accordance with their requirements.

In view of their future careers, schoolboy mathematicians are divisible roughly into three classes—those who will make a profession of mathematics, those who will apply mathematics to science, and those who will, after obtaining academic honours, entirely sever their connection with the subject. To the last of these the question of syllabus is of comparatively small importance. But to the first and second it is of the utmost importance, and especially to the second, as it is essential to a man who for several years studies mathematics with an ulterior object in view that, while he should acquire a thorough grasp of the principles of the subject, he should not be forced by examining bodies to apply himself to what can only be regarded as intellectual pastimes; nor even in the case of the first can great skill in work of this class rank *pari passu* with a grasp of principle.

Consider the case of an able schoolboy who makes mathematics his chief study between the ages, say, of fifteen and nineteen; this period should suffice to give him a working knowledge of three-dimensional analysis, integral calculus and differential equations with their applications to the mechanics of solids, in addition to the subjects now required by the colleges, were it not for certain side issues which have arisen from the latter and assumed stupendous proportions. Foremost among these stands the excessive measure of attention given to the analysis of curves of the second degree. These form naturally a small section in a treatise on analytical geometry; yet while the far-reaching principles of the latter are lightly passed over, there is scarcely a method so abstruse or an artifice so petty that it may not give rise to a question in an entrance scholarship paper if its bearing be upon conic sections; so that no less than a third of a schoolboy's mathematical hours are frequently sacrificed to these curves. Their real interest is due, firstly, to their appearance in astronomy (the properties there required are few, and might be treated in the appendix of a text-book on dynamics), and, secondly, to their adaptability to treatment by pure geometry, the direct methods of which lend them an interest which is alien to every other branch of mathematics, and supply a mental discipline which is elsewhere unattainable. On this alone rests their title to rank as a separate subject.

But this, though the most aggravated, is not the only instance of the kind. The time spent on advanced trigonometry is out of all proportion to its practical or educational value; the subject contains an introduction to the use of the complex quantity which properly forms part of the theory of functions, and includes a number of highly specialised problems which have no place in a syllabus so elementary as to exclude the integral calculus. A similar waste is caused by several large classes of questions, especially some on series, the ability to solve which implies nothing but an effort of memory, and by other fragments of high subjects which are thrust upon boys at an early stage and made artificially difficult by isolation from their proper context.

The above criticisms are not made in any spirit of hostility to examiners, who in framing their papers are trying to obviate the shortcomings of a system which is out of date and in need of radical reform. Five decades ago it was doubtless advisable, in view of the then state of school mathematics, to limit the entrance scholarship course to a few subjects, but under new and improved conditions is not an extension of syllabus preferable to the interweaving with these of a quantity of matter which, valuable as it may be to the problem setter, is for the student little else than a barrier to his progress?

But if the examinations in mathematics and science are to be brought into harmony, it is not only in the former that a new regime is needed. Under present conditions a boy could learn at school nearly the whole of the mathematics necessary for an advanced physical course. But to do this would jeopardise his chance of obtaining a first class in the science tripos unless the authorities recognised the value of his mathematical training by a substantial equivalent of marks, so that he might make a mathematical entrance scholarship the preliminary to a science course. For those who have not a taste for theory it would still be possible to adopt an experimental regime from the outset, though it is questionable whether they could in the long run bear comparison with men who had cultivated a faculty which it is no exaggeration to call a sixth sense. The glory of Cambridge and her highest traditions are centred in the names of her mathematical physicists. But the environment which surrounded Maxwell and Kelvin no longer exists. And to-day the growth of subjects and the consequent tendency to specialisation have gone far to materialise the phantom barrier which separates the practical from the theoretical, and have laid on the authorities the burden of creating a new system which shall be capable of reproducing the giants of the past.

Dulwich College, March 13. C. A. RUMSEY.

The Morphology of Pleuronectidæ.

IN the *Memoir* on the Plaice by Messrs. Cole and Johnstone, reviewed in NATURE of March 20 (p. 459), there is a reference to Steenstrup's work on the metamorphosis of Pleuronectidæ which I think the reviewer would have done well to correct. The statement to which I refer is the following:—"This supposition (that the left eye passed through the substance of the head to reach the ocular side), absurd as it may seem to us now, was in fact believed by such an observer as Steenstrup." The truth of the matter is that Steenstrup did not believe any supposition, absurd or otherwise, on the subject, but stated from actual observation that in certain larval Pleuronectidæ the eye of one side passed through the tissues of the head and emerged on the other side. The form in question was long known as Plagusia, and is now known to be the larva of Rhamboidichthys. The truth of Steenstrup's observations was fully confirmed by Alexander Agassiz at Newport, R.I.

On the other hand, in the "Story of Life in the Seas," by Prof. S. J. Hickson, it is stated that in the young of the soles the eye of one side passes through the head to the other side. This is equally incorrect.

Messrs. Cole and Johnstone also state that the Gadidæ are the nearest relatives of the Pleuronectidæ, and promise to show that the morphological differences between the cod and the plaice, apart from the question of symmetry, are comparatively few and unimportant. I cannot find in the *Memoir* that they have redeemed this promise, and the morphological similarity of the two forms is contradicted by the authors themselves on p. 185 of the *Memoir*. I believe it could be shown by proper investigation that the morphological differences between these two fish are numerous and profound.

I think some explanation was due from the reviewer concerning Dr. Woodward's "startling discovery" that in Cretaceous times Teleostei of the Clupeoid type had already translocated the pelvic fin into the jugular position. I have not yet had the pleasure of seeing Dr. Woodward's latest volume, but a Clupeoid with jugular fins seems to me indeed a startling discovery.

Penzance, March 22. J. T. CUNNINGHAM.

WHEN writing I was well aware that the sentence Mr. Cunningham quotes was not happily construed, but seeing that comment (like that of Mr. Cunningham himself) would needs be hypercritical, I allowed the matter to pass, in consideration of the context and of the desire to keep my review within bounds.

Concerning the Cretaceous teleostean described by Dr. Smith Woodward, I can only express my surprise that Mr. Cunningham should be so neglectful of the current literature of his subjects as to be unaware of its occurrence. With the rest of his letter I have no concern.

THE WRITER OF THE REVIEW.

Sun Pillars.

I HAVE been deeply interested in the correspondence in NATURE bearing on the appearance of sun pillars, and particularly so in the communication of Prof. Johnstone Stoney (p. 465).

The display of March 6 mentioned by the Rev. Guy Bridges and Mr. W. A. Knight was not visible here; but a very noteworthy occurrence of the phenomenon took place here on December 3 last and another on January 7 last, and there was one feature common to both of these events which has not been mentioned as occurring in relation to those recorded by other observers, so far as I am aware, but which seems to me to be a prime factor in the causation of the phenomenon under consideration, and it is this:—Before, and after, the actual time of the setting of the sun, during my own observations, there was a strong display of cirrus cloud in the "true cirrus" form of parallel bars, which appeared to run at right angles to the track of the setting sun, and roughly parallel, of course, to the horizon. As the setting sun neared the horizon, these bands of cloud became magnificently iridescent, displaying the spectrum colours of the rainbow, with the red nearest the horizon. As the sun set further the colours faded, beginning first at the red and following on in succession to the violet until this colour alone remained visible. Then ascended a beautiful pillar of a violet colour in exquisite shades, ascending gradually to a height of somewhere about twenty degrees above the horizon and then fading away slowly.

It seemed to me that the occurrence depended on (*a*) the presence of cirrus cloud (ice spiculæ); (*b*) these clouds must be in a banded or striated form; (*c*) they must lie at right angles to the track of the sun; and (*d*) these clouds must, of course, be present in the immediate neighbourhood of the setting sun. There are, besides, certain atmospheric conditions which seem to be desiderated in order to favour opacity, as dryness of the air, with calmness in its movements, and, I believe, a comparatively high barometric pressure. At the time of my

observation of December 3, the relative humidity of the air was 75 per cent., the wind calm, and the barometer, corrected to 32° and sea-level, 30·284 inches. On January 7, relative humidity was 76·5 per cent., wind faint; barometer 30·499 inches. The altitude of this station is 480 feet; lat. 54° N., long. 1°.36 W. G. PAUL.

Corporation Observatory, Harrogate, March 24.

THE sun pillar described by your correspondents was very well seen from the railway between Netley (5.40) and Southampton (6 p.m.), and lasted, I think, more than half an hour. It was visible before and after sunset. The upper air at the time was remarkably calm; the morning had been foggy, and the morning of March 7 was also foggy on the ground. Observation of the upper clouds on the morning of the 6th, and at the time of the phenomenon, showed an extremely slow movement from the north-west, barely noticeable between telegraph wires overhead. At 9 a.m. on the 7th cirrus was moving very slowly from about north, and at noon from north-west.

R. RUSSELL.

Condercum, Alum Chine, Bournemouth, March 24.

THE accounts of this rather rare phenomenon (as it seems to be) come (so far) only from the south-west of England. It is, therefore, worth while adding the following as seen at Oxford by myself and friends:—

March 6, 6.18 p.m.—A vertical pillar of flame-coloured light, springing probably from the sun below the horizon, quite parallel-sided, about ⅜° wide and 6° high, careful measurements, perfectly steady for the 10 minutes that we were able to look that way. We thought there was a condensation of light, as of a faint mock sun, about 4° above the horizon. It was fading off downwards appreciably at the last moment.

Littlemore, Oxford. W. J. HERSCHEL.

IF the phenomenon of so-called "sun pillars" can only obtain when the atmosphere is "quite free from convection currents . . . (which it seldom is)" [see NATURE, March 20], is it not reasonable to suspect that the thing seen on March 6 was *not* such an atmospherical phenomenon? since it was viewed east and west from Brighton to the Cornish coast and northwards to High Barnet and Carmarthen Bay, so far as has been already ascertained.

If the barometrical and thermometrical readings, wind velocities and directions over this wide area on the 5th, 6th and 7th inst. could be obtained, an examination of these would go far to settle the question. CATHERINE O. STEVENS.

Bradfield, Berks, March 31.

Sounds Associated with Low Temperatures.

THE whistling or squeaking of snow under foot at low temperatures is a familiar phenomenon to residents in such climates as that of Canada. The sound is in strong contrast to the crunching of snow at the freezing point.

I suspect that "walking about the sheds" in the letter quoted by Sir Wm. Preece (p. 487) means walking over snow-covered ground between the sheds. J. D. EVERETT.

11 Leopold Road, Ealing, March 29.

I HAVE, I think, frequently heard the sounds mentioned in the letter sent to you by Sir William Preece; but if the sounds I mean are the same as those there described they are not necessarily associated with low temperatures, though they would be more likely to be noticed when the ground is frozen. The sounds to which I refer are to be heard near palings or sheds made, as they frequently are, with overlapping boards. The explanation I have always supposed to be as follows:—If the ground is sharply struck, with the boot for instance, the sound thus made will be reflected back by the ends of the boards; as each of these ends is further from the listener than its neighbour, the echoes will come back at intervals depending on the distance of the observer from the paling and on the width of the boards; if the boards are of equal width, the echoes will come back with nearly equal intervals between them, thus producing a musical note. If the ground is frozen, the sharp sounds necessary will be produced when walking by one's boot striking the ground; but the same sounds may be produced in dry weather and especially when walking on gravel. I have often observed the musical note, but never where such an explanation would not be possible. Wooden palings are not, however, necessary; I have heard the same thing when walking past iron palings, more particularly, as is to be expected, when the uprights have a square section. CHARLES J. P. CAVE.

Binsted, Cambridge, March 31.

CENTRAL AND SOUTH AMERICA.[1]

CENTRAL AMERICA and the West Indies are attracting so much attention at present that a comprehensive description of them is of especial value to all who are watching the growth of political power in the New World. Hence we may welcome Mr. Keane's work, which, *inter alia*, treats of their history, physical geography, climate, flora, fauna, ethnology and industries, as well as of their financial and commercial statistics. The volume, although purporting to be a "new issue," might well claim to have no relation to the old one, edited, a quarter of a century ago, by the well-known naturalist H. W. Bates; for the knowledge of the region which has accumulated during the interval has been largely utilised, although not brought up to date in some important respects. Besides ten carefully executed maps, not overloaded and confused by unimportant names, the work contains numerous illustrations.

Mr. Keane opens his subject with a comprehensive chapter on the physical and biographical relations of the countries under consideration. "The present Central American mainland, like the Southern continent, formed, originally, a vast insular region, which was gradually consolidated in Tertiary and later times. It constituted a great archipelago, which stretched, for about 770 miles, in a south-easterly direction from Tehuantepec to Panama, and presented certain analogies to the West Indian insular world, with which it is in fact connected by at least two chains of islets, reefs, and partly or wholly submerged marine banks. . . . It is difficult to realise the fact that the 'American Mediterranean,' as the Gulf of Mexico and Caribbean Sea are often called, has a circuit from Cape Sable round to the Bahamas of no less than 12,000 miles. . . . The volume of water (the Gulf Stream) rejoining the equatorial current north of Florida strait, though relatively small, forms none the less a liquid mass about fifty-five miles wide and 450 fathoms deep moving at the rate of from two to six miles an hour, and is thus equivalent to as many as 300,000 rivers as copious as the Mississippi." It may be remarked that Maury is contented with giving the flow of the Gulf Stream through this strait as 1000 times the volume of the mighty river mentioned.

Mr. Keane discusses at length the ethno-geographical relations of the almost numberless tribes which have made the lands bordering the Gulf of Mexico and Caribbean Sea such an interesting study, and he concedes to the Toltec, Aztec and Maya peoples a high degree of civilisation. Most writers do the same, as they let their imagination revel in the romantic accounts of the conquest of Mexico and the descriptions of the ruins found from New Mexico to Panama; but it may be doubted if any of the tribes of Indians who occupied that region ever reached a higher grade than the "Upper Status of Barbarism" so admirably defined by Lewis H. Morgan in his "Ancient Society."

As to the Carib race, the cradle of which Mr. Keane rightly fixes in the heart of South America, they wandered north to the shores of the Caribbean Sea, to which they gave their name, and which recognised, throughout its

[1] Stanford's "Compendium of Geography and Travel" (new issue). "Central and South America." Vol. ii. Central America and West Indies. By A. H. Keane, F.R.G.S. Edited by Sir Clements Markham, K.C.B., F.R.S. Pp. xxiv+496. (London: E. Stanford.) Price 15s.

islands and coast lands, their all-conquering predominance. In fact the Carib, a born navigator, was the connecting link between North and South America, and freely navigated the Gulf of Mexico and the Caribbean Sea for purposes of war or trade.

Commenting on the "pre-Columbian cultered Toltecs of Mexico," the author shows how these were pushed aside or driven southward by the invasion of the Nahuas from the north, who extended their conquests, by the Pacific coast, into Guatemala and Yucatan, and "penetrated beyond this region into Nicaragua, everywhere founding settlements amid the surrounding aborigines." But the Nahuatlacâ (Aztec) race really overran Central America as far south as the Isthmus of Panama. Vasquez de Coronado, in 1564, met a cacique, Iztolin, on the southern shore of Almirante Bay, who conversed with him in the Nahua tongue; and Ferraz has shown that numerous existing geographical names in Costa Rica are of Nahua derivation. But Panama was probably a debatable ground between them and the Indians of Colombia, or between them and the Caribs who occupied and crossed the isthmus and extended their raids to the Pacific coast of Colombia, which was populated by the Chocoamas. These, according to Codazzi, spoke Cueva, a mixture of Carib and Chocoama. That the Panama Indians were in communication with those of Nicaragua (which were, in turn, in contact with those of the Mexican tableland) is also proven by the first Spanish exploring expedition sent northward (1516) from the Pacific side of the isthmus, near which they found a large bay, where the Chinchiris Indians gave the information that there was a communication between the two oceans through a great interior lake (Nicaragua).

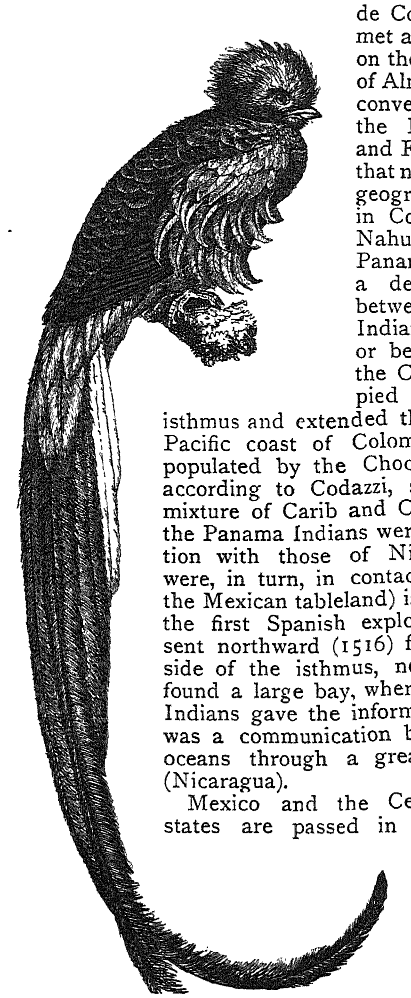

FIG. 1.—Quetzal.

Mexico and the Central American states are passed in review by Mr. Keane, and their history, geography, physical features, &c., receive such attention as is possible within the limits of the volume. Regarding the history of the first, he says, "the endless revolutions and political disorders of all sorts which followed the War of Independence produce a sense of weariness accompanied by a feeling of surprise that the Mexican people could have ever recovered from such a succession of overwhelming calamities." This is true; but it would have been useful to state that almost all of these revolutions represented the struggle of the Liberal party to shake off the baneful grip of the Church, which, in 1827, had 150 convents scattered over Mexico, and, in 1833, held more than one-third of the country in mortmain. Moreover, Europe was responsible for aiding the clergy in the last grand struggle of the latter to retain their power, through the establishment of an Imperial Government under Maximilian, backed by a French army. It was the most terrible and desolating war that Mexico ever saw; but the effort of the Church was a disastrous failure—the greatest of Mexicans, the Indian Juarez, was the victor, and the Constitution of 1857 and the Laws of Reform of 1859 remained triumphant, and became the basis of the subsequent remarkable progress of the country.

Quoting a careless writer, Matias Romero, Mr. Keane gives Mexico 15,000,000 inhabitants and estimates the whites at 19, the aborigines at 38 and the mixed at 43 per cent. of the population; but such statements are only based on personal judgment. I should be inclined to estimate the aborigines at at least one-half of the entire population. It is a question if the aboriginal blood is not stronger than the Spanish, and if it will not, in the long run, aided by climate and environment, *indianise* the latter, unless arrested from the north.

Remarking on the mineral wealth, Mr. Keane gives the total mintage of Mexico since 1537 at 706,000,000*l*. This is probably understated; the eminent statistician Miguel Lerdo Tejada, in 1853, in an elaborate statement, gave the total amount coined, from the conquest up to 1852, at 3,562,204,897 dollars (pesos), of which 110,000,000 dollars remained in the country. The amount exported did not include contraband shipments of uncoined silver, which were enormous.

It is impossible within the reasonable limits of a review to comment upon all the interesting and varied data contained in Mr. Keane's valuable book. Some of the countries, however, of which it treats have already outgrown it; Spanish America, with all its turmoil, moves faster than Europe. In speaking of the two principal Atlantic ports of Mexico, Mr. Keane says that below Tampico, "six miles above the mouth of the Panuco river, this is so shallow that vessels drawing over nine feet have to ride at anchor outside the bar"; and as to Vera Cruz, "there is no harbour at all. . . . Vera Cruz should certainly have been founded at Anton Lizardo, fifteen miles further south, which has the only good harbour in the Gulf." These statements should be modified somewhat; the bar of Tampico has been deepened, and admits ships drawing twenty feet of water. The total net register tonnage of vessels entering the port now exceeds that of Vera Cruz. The fine port works of the latter (enclosing an area of nearly a square mile) give safety for ships of heavy draught. As to Anton Lizardo, as a harbour, its safety against "northers" could only be assured by building a very long breakwater on the reef which partially protects it and which is only visible at low water.

Reaching the Central American States, the author properly describes Guatemala as "almost an Indian republic." Here the population double their chances for the efficacy of prayer by worshipping at a Christian altar with images of their heathen deities hidden behind it. The physical features of the country, its products, character of its people and their Government are similar to those of the densely populated contiguous state of Salvador. Honduras, which has been the victim of financial depredations from abroad rivalling in magnitude its almost unequalled natural resources, is well and vividly outlined. It is the richest in mineral wealth of all the Central American States. Nicaragua and Costa Rica are treated at some length. The former is distinguished by three physical zones:—"(1) the Mosquito seaboard, partly of coralline (marine), partly of alluvial formation; (2) the uplands of the interior, with the Cordillera de los Andes forming part of the original continental framework, and extending from Mosquitia to the great depression which is now flooded by lakes Nicaragua and Managua; (3 the coastlands between the lakes and the Pacific, which are mainly of igneous origin and form a southern continuation of the Salvador volcanic system. . . . Thanks to a

mean altitude of from 2000 to 3000 feet above the sea, the central uplands, including the Atlantic slopes of the Nicaraguan backbone, enjoy a relatively mild climate, generally healthy and suited for European settlement." Of Costa Rica, "probably 275,000, out of a total population of 294,000, have already been fused in a somewhat homogeneous Ladino element of Spanish speech and culture. As in Salvador and Nicaragua, the people are concentrated in the fertile and salubrious volcanic districts on the Pacific slope." Mr. Keane's description of the principal West Indian islands is admirable and varied, and enables the reader to understand their importance in the general movement of the world; but the voluminous publications of the United States Government, in 1900, relative to Cuba and Puertorico, might have been consulted with advantage. Saving the defect that much of the industrial, financial and commercial data are not brought up to date, the volume is an extremely useful and instructive compendium of the subjects of which it treats, and does great credit both to the publisher and the author. One of the illustrations is reproduced on the preceding page. GEORGE EARL CHURCH.

THE MALDIVE AND LACCADIVE ARCHIPELAGOES.[1]

FEW oceanic island groups are of greater interest to the students of the science of "distribution" than the Laccadives, Maldives, Chagos and Seychelles, since they appear to be the last remnants of a land connection between India and Madagascar. For instance, Dr. W. T. Blanford, in his presidential address to the Geological Society for 1890, after mentioning that there appeared to be evidence of deep water between the banks on which the above-mentioned islands are situated, proceeded to say that he believed a fuller knowledge of the contours would reveal the existence of a bank connecting the whole series from India to Madagascar. "Even should this not be case, the evidence of a land-connection appears so strong that it may be a question whether the whole of the ocean-bottom between Africa and India may not have sunk to its present depth since Cretaceous times."

In addition to this special point of interest, the coral-reefs of the Maldives, Laccadives and Ceylon have an interest of their own in regard to their mode of formation and growth, the fauna by which they are inhabited, and the evidence they afford either of upheaval or of subsidence in this part of the Indian Ocean. The managers of the Balfour studentship, with the assistance of donations from the Government Grant Committee of the Royal Society and the British Association, were therefore well advised in selecting this area as one where a careful and detailed geographical and zoological survey would be likely to yield results of the highest scientific importance. So far as can be judged from the small section of the work now before us, Mr. Gardiner, ably seconded by Messrs. Borradaile and Cooper, appears to have carried out his task with great thoroughness and success. A part of the time, it is true, he was incapacitated from work by illness, but during his absence the researches were carried on with vigour by Mr. Cooper, who took no less than eighty-eight dredgings in five different atolls.

[1] "The Fauna and Geography of the Maldive and Laccadive Archipelagoes, being the account of the work carried on and of the collections made by an expedition during the years 1899 and 1900." Edited by J. S. Gardiner. Vol. i., part i. (Cambridge: University Press, 1901.)

Until the appearance of the complete work, which we gather will run to at least two volumes, we cannot, of course, lay before our readers the editor's conclusions with regard to the important problem mentioned at the commencement of this article. Neither can we refer to the general *facies* of the fauna of these islands. Our notice must accordingly be restricted to the general introduction to the work and the four chapters which (together with a description of certain sections of the fauna) constitute the part before us.

For reasons connected with the meteorological conditions prevailing in the Indian Ocean, it was decided to devote the summer of 1899 to a thorough survey of Minikoi, the most southern atoll of the Laccadives. This island forms the subject of two out of the four chapters already published, and its history is to be continued in those which follow.

In the introduction, Mr. Gardiner refers to the enormous numbers of the delicate shells of the cephalopod Spirula met with on the northern end of one island. On inquiry from the natives he found that they were quite familiar with the complete mollusc, which appeared in numbers during the winter of 1897. Strangely enough, however, the creature seems to be extremely local, since it is quite unknown to any of the other islanders.

In the chapter on its coral islands, the author remarks that the Indian Ocean gives little clue from its topography to the character of the foundations of the various groups; and in this respect is unlike the Pacific, where the groups run more or less nearly parallel to one another and to the adjacent continent. In one respect the two oceans present a striking similarity, namely, in the absence or paucity of coral-islands on their eastern[1] sides. In the Pacific this absence is complete; in the Indian Ocean it is broken only by Cocos-Keeling and Christmas Islands. In the Indian Ocean this scarcity of islands on the eastern border is, so far as it goes, in favour of the view that the numerous islands on the western side formed part of a land-connection. This belt between Madagascar and India is cut, says the author, to a depth of more than 2000 fathoms in three places, to wit, between the Maldives and Chagos, between the latter and Saya de Malha Bank, and again between Farquhar Atoll and Madagascar. "These channels divide the coral-reef areas into four sections, which may be respectively termed the Malagasy, Seychelles, Chagos and Maldive." These four sections are then discussed in detail.

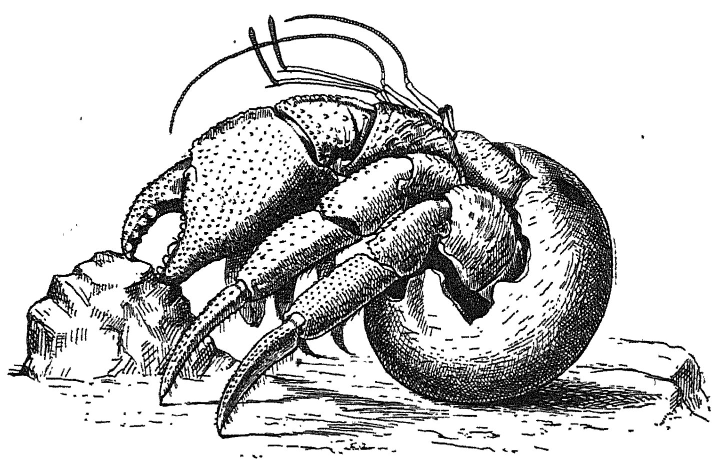

FIG. 1.—*Coenobita clypeatus* using a broken cocoanut as shell.

Chapters iii. and iv. are devoted to part of the descrip-

[1] The author writes "western," but he obviously means "eastern."

tion of Minikoi, of which a map is given. Although at one point the land is gaining on the lagoon, in others it is gradually diminishing, and the author prophesies that in course of time the sea will make a clean sweep of some parts of the atoll.

Much attention is devoted to the mode of formation of a coral conglomerate found in Minikoi and elsewhere at the base of the outer beach. From the presence of this conglomerate and other evidence, the author concludes that an elevation of at least 24 feet must be admitted to have taken place in Minikoi, and this during the time that it has existed as an atoll. "The presence of conglomerate masses," he adds, "I can only regard as indicating the existence of former land in any position where they now occur. The land there must have at one time extended round the whole island with only a single break, perhaps to the north, with lower parts here and there, where boat-channels across the reef now exist." Minikoi was indeed once apparently very like some of the low coral-islands of the Maldive group in the Indian Ocean and the Ellice group in the Pacific. For the final chapters on Minikoi we must await another fasciculus of the work.

The groups of the Minikoi fauna included in this fasciculus comprise the Hymenoptera, by Mr. P. Cameron; the land crustaceans, by Mr. L. A. Borradaile; and the nemertean worms, by Mr. R. C. Punnett. Among the second of these perhaps the most generally interesting group are the land hermit-crabs of the genus Cœnobita. Like the great cocoanut crab (*Birgus latro*), these crabs have forsaken the sea for a life on land, although (unlike the former) they still retain the habit of sheltering the abdomen within a shell or some such covering. In the case of a specimen of which the figure is here reproduced, the abdomen is encased in the broken shell of a cocoanut. Among the nemertean worms, a genus hitherto known only from Amboina has been met with again at Minikoi. R. L.

PROF. MAXWELL SIMPSON, F.R.S.

Maxwell Simpson, ninth and youngest child of the late Thomas Simpson, was born at Beech Hill, co. Armagh, Ireland, on March 15, 1815. Educated at a private school in Newry, he thence proceeded to Trinity College, Dublin, where he took his Arts degree, and subsequently entered the School of Medicine. In 1847 he graduated as Bachelor of Medicine in Trinity College; but already he had been strongly attracted towards the study of chemistry, and instead of settling down to the practice of physic, he now became associated, as lecturer in chemistry, with the medical school of Park Street, Dublin. This school had been established about 1824 by a number of physicians and surgeons, and had included among its teachers James Apjohn, subsequently professor of chemistry in the University of Dublin. From Park Street he was transferred to the Peter Street School of Medicine, where he remained for a few years.

Inspired, however, by a profound love for science, the limitations incidental to such a post grew irksome to him; the desire to secure adequate outlet for his intellectual energies, to prosecute his own inquiries, and to enjoy the communion of fellow-workers intensified with time, until finally, casting aside all material considerations, he relinquished his teaching and proceeded to the Continent, where, associated with some of the most eminent chemists of the day, he was free to breathe the congenial atmosphere of research.

Plunging with characteristic energy and enthusiasm into work, he soon became productive. In 1851 he studied with Kolbe at Marburg, then under Bunsen at Heidelberg, conducting in the laboratory of the latter an investigation on which his first original paper was based; this communication, "On two new Methods for the Determination of Nitrogen in Organic and Inorganic Compounds," published in the *Journal* of the Chemical Society (vi. 289) and in the *Annalen der Chemie und Pharmacie* (xcv. 63), foreshadowed the accuracy and thoroughness which were to mark his later work.

Moving next to Paris, and entering the laboratory of Wurtz, his attention naturally became centred on organic chemistry, and here his capacity for work was quickly manifested; commencing with a paper on the "Action du Brome sur l'Iodure d'Aldéhydène," read before the Académie des Sciences on March 1, 1858, one memoir followed another in rapid succession. In April he made a communication "Sur une Base nouvelle obtenue par l'action de l'Ammoniaque sur le Tribromure d'Allyle," another on the same subject in August, and a third in November on the "Action du Chlorure d'Acétyle sur l'Aldéhyde"; these he followed up by two papers (*Proc.* Roy. Soc., ix. 725 and x. 114) "On the Action of Acids on Glycol." On April 25, 1861, Prof. Frankland communicated, on his behalf, to the Royal Society the first of two important papers "On the Synthesis of Succinic and Pyrotartaric Acids," in which he showed that the former, built up from ethylene, through the dibromide and corresponding cyanide, is identical with common succinic acid; the latter, from propylene bromide, with the pyrotartaric acid got by distilling natural tartaric acid—thereby establishing the chemical constitution of both. This excellent piece of work met with due recognition, and in 1862 Maxwell Simpson was admitted a Fellow of the Royal Society.

Two other communications appeared (*Proc.* Roy. Soc., xi. 590 and xii. 278) "On the Action of Chloride of Iodine on Iodide of Ethylene and Propylene Gas," and, almost concurrently with these, two more, now classical, "On the Synthesis of Tribasic Acids" (*ibid.* xii. 236, and *Journ.* Chem. Soc., 2, iii. 331); here it was shown that from allyl tribromide, a corresponding tricyanide can be obtained, which by saponification yields a salt of tricarballylic acid—this substance is an immediate derivative of glycerine, and "bears the same relation to citric acid that succinic bears to malic acid."

It is not possible within these limits of space adequately to notice Simpson's work or its bearing. Of his further papers may be mentioned: "On the Acids that may be derived from the Cyanides of the Oxy-radicals of the Di- and Tri-atomic Alcohols"; "On the direct Transformation of Iodide of Allyle into Iodide of Propyle"; "On the Action of Chloride of Iodine upon Organic Substances"; "On the Formation of Di-iodacetone"; "On the Formation of Succinic Acid from the Chloride of Ethylidene"; "On a new Compound formed by the direct union of Aldehyde and Anhydrous Prussic Acid" (with Dr. Gautier); "On the direct Transformation of Chlor-iodide of Ethylene into Glycol"; "On some new Derivatives of Acetone"; "On the Brom-iodides"; "On the Determination of Urea by means of Hypobromite of Soda" (with Mr. C. O'Keeffe), and a paper (*Proc.* Roy. Soc., xxvii. 120) "On compounds of Silver Iodide with Alkyl Iodides." Of the above work, that described in the paper on aldehydes and hydrocyanic acid is especially important, leading, as it did, to the synthetical production of one of the forms of lactic acid.

In 1872, Maxwell Simpson was appointed to the chair of chemistry in Queen's College, Cork, an office which he resigned after nineteen years of service.

His power was by no means confined to the research laboratory; as a lecturer he possessed in a high degree that gift of luminous exposition which is the product of quick and accurate memory, clear intelligence and ready command of language. Simple and unaffected, genial of manner, though strong in the courage of his convictions; direct and original in thought and speech, Simpson's

personality was forceful, interesting and lovable. Endowed as he was, it may seem strange that he did not establish a school of chemistry in Cork. But the reason is not to be found in the man—rather in his surroundings. Placed, as he was, in a sparsely populated district, where poverty is, unhappily, the rule, where chemical manufactures are but few, and where the demand for highly trained chemical knowledge of any sort is practically non-existent, the result flowed almost inevitably from the conditions.

At various times he acted as examiner in chemistry to the Civil Service of India, the Civil Engineering College, Coopers Hill, and the Royal Military Academy, Woolwich; he was an Honorary Fellow of the King's and Queen's College of Physicians; received the degrees of M.D. and LL.D. (both *honoris causa*) from the University of Dublin; was a senator of the Queen's University; Fellow of, and examiner in, the Royal University of Ireland, from which he received the degree of D.Sc. (*honoris causa*); he was also selected as president of the section of chemistry of the British Association at its meeting in Dublin in 1878. In addition, he was for several years a member of the council of the Chemical Society, by which he was elected, during the years 1872–74, to the office of vice-president.

On February 26, Maxwell Simpson passed away in London; his work remains, a worthy and enduring memorial to his love for that science which he so generously enriched. A. E. DIXON.

NOTES.

PROF. E. C. PICKERING announces that he has received from a friend a gift of twenty thousand dollars (4000*l.*) for the benefit of the Harvard College Observatory. It is proposed to expend about one-half of this fund in extending the present building in which the astronomical photographs are kept, so as to provide for the adequate storing of this collection with its probable increase for many years. These photographs furnish a history of the entire stellar universe for the last twelve years, and is not duplicated elsewhere. A portion of the remainder of the gift will be used at once to provide for the study of objects of interest on the photographs, as hitherto only those of special importance have been examined.

THE Raoult Memorial Lecture of the Chemical Society was delivered by Prof. van 't Hoff on Wednesday of last week. Shortly after Raoult's death, a year ago, a short account of his career was given in these columns (vol. lxiv. p. 17). Prof. van 't Hoff remarked that the scientific work could be conveniently considered as belonging to three periods of Raoult's life—physical, chemical and physiological. As a typical research of the first period he mentioned the study of the heat evolved by chemical reactions in the voltaic cell and that due to the electric current. Later, Raoult directed his attention to subjects of a more purely chemical nature, such as the influence of solar radiation on the inversion of cane sugar, and the absorption of ammonia by saline solutions. His physiological work included studies of the presence of copper and zinc in the animal organism and the influence of carbon anhydride on respiration. But Prof. van 't Hoff pointed out that the researches which made Raoult's name famous as a scientific investigator were those which led to the establishment of a definite connection between the lowering of the freezing points and of the vapour pressures of solvents by the presence of dissolved substances. This led Prof. van 't Hoff to the important generalisation that the osmotic pressure of a dissolved substance bears a definite relationship to the pressure it would exert if it were in a state of vapour—a theory which has been of immense service in elucidating the nature of solutions and has also led to the theory now widely accepted as to the existence in dilute salt solutions of the ions of the dissolved substance.

WE regret to see the announcement of the death on Good Friday of Mr. G. F. Wilson, F.R.S., whose scientific work included the discovery of the means of obtaining pure glycerine, and numerous papers on horticultural subjects. Mr. Wilson was in his eightieth year.

LORD KELVIN is expected to arrive in New York on April 19. *Science* states that a reception will be given in his honour on the evening of April 21 by Columbia University, the American Institute of Electrical Engineers, the New York Academy of Sciences and other scientific societies.

ON Tuesday next, April 8, Dr. Allan Macfadyen will deliver the first of a course of three lectures at the Royal Institution on "Biological Inquiry"; on Thursday, April 10, Prof. Dewar will begin a course of three lectures on "The Oxygen Group of Elements." The Friday evening discourse on April 11 will be delivered by Prof. Dewar on "Problems of the Atmosphere," and on April 18 by Sir John H. A. Macdonald, his subject being "The Autocar."

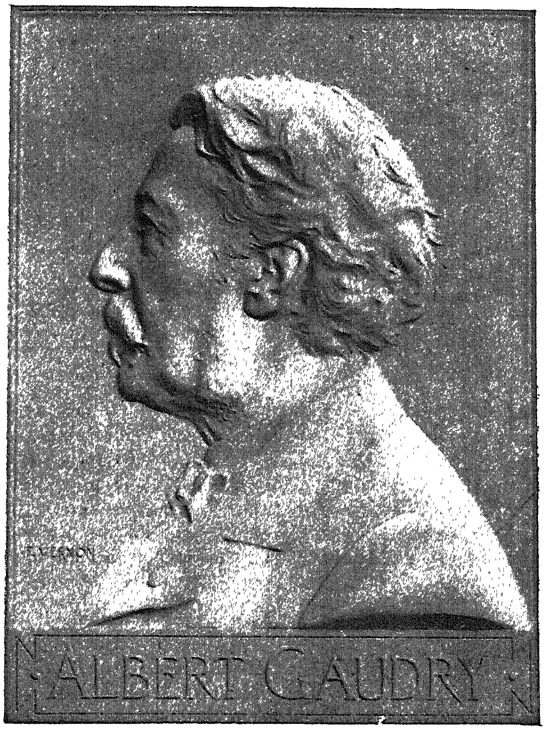
THE Berlin correspondent of the *Times* states, upon the authority of the *Lokalanzeiger*, that a scheme is under consideration by the German Imperial authorities in accordance with which the chief commercial nations, especially England, France and the United States, will be invited to send representatives to an international congress, the object of which will be to arrive at an agreement forbidding the establishment of any monopoly in wireless telegraphy on the high seas. This step, it is stated, is the direct consequence of the refusal of the Marconi station on the Nantucket lightship to enter into communication with the *Deutschland* during its homeward journey with Prince Henry of Prussia on board.

WE learn from the *Times* that the University of Chicago has commissioned Mr. Alleyne Ireland to report on the financial, commercial and social conditions of all the European colonies in the Far East, where the circumstances appear both geographically and historically to bear some resemblance to the general situation of the Philippines. Mr. Ireland will visit Burma, Siam, the Federated Malay States, the Straits Settlements, Sumatra, Java, British North Borneo, Sarawak, French Indo-China, Tonking, Formosa and Hongkong. After making an investigation of the general condition of the Indo-Malayan people under British, Dutch, French, and native rule, he will then go to the Philippines in order to examine the conditions of those islands from the comparative point of view. It is anticipated that his inquiry will occupy about two years.

AT the request of the U.S. Senate, the Secretary of Agriculture has reported upon the condition of the American bison. In his summary he states that this species is on the verge of extermination. Scarcely a handful now remain of the millions which formerly roamed over the plains of the west. Only two small herds of wild buffalo are in existence in the United States—one in the Yellowstone Park, the other in Lost Park, Colo. There are no wild buffalo in Canada, except in the Peace river country, where a few woodland buffalo, believed to be a different species from the American plains buffalo, still exist. A number of buffalo have been domesticated and half-domesticated, there being three important herds in addition to the small herds in zoological parks and in the hands of private individuals. It is suggested that if the Government would acquire possession of a considerable number of full-blooded animals the absolute extermination of the species might be long delayed.

The fourteenth International Medical Congress will be held at Madrid on April 23-30 of next year. The *British Medical Journal* states that in almost all the countries of Europe and America local organising committees have been formed. The Spanish Minister for Foreign Affairs has invited all Governments to send representatives. A similar invitation has been sent to all universities and medical schools, and to the principal medical societies in all countries. Among the numerous applications for membership which have up to the present been sent in are the names of eighty-five delegates, and there is every prospect of a most successful meeting. Among the notabilities of the medical world who have promised to deliver addresses are Profs. Pavlov, Maragliano, Thomson, Laache, Waldeyer, Cajal and others. Almost all the various sections have arranged their programmes of discussions, and they are now grappling with the task of selecting men to open them. A preliminary programme, including not only the official list of discussions, but the titles of communications offered, will shortly be issued.

As already announced, the jubilee of the scientific career of the eminent palæontologist, Prof. A. Gaudry, was celebrated at Paris on March 9, when many of his old pupils, friends and admirers assembled to do him honour and to offer him a medal commemorative of his services to science. Delegates were present from numerous learned societies and académies, including our own Royal Society; and addresses were delivered by M. E. Perrier, director of the Natural History Museum, where the celebration was held, M. M. Boule and M. Liard. The accompanying illustrations from *La Nature* show the medal which was presented to Prof. Gaudry as a slight mark of appreciation of his work in palæontology and the honour it has brought to France and to the museum with which he has been so long connected as student, assistant naturalist and professor.



The Russian Geographical Society has sustained another heavy loss by the death of General Mikhail Vasilievich Pyevtsoff. He was born in 1843,[1] received his education in a military school, and next in the Academy of the General Staff, and after having finished his studies remained for fifteen years at the General Staff at Omsk, making important journeys in Dzungaria and north-western Mongolia. He also took part in the great surveys which were made in 1880 on Chinese territory in connection with the tracing of the boundary between China and Russia. The results of the first two journeys were embodied in papers published in the *Memoirs* of the West Siberian Geographical Society, the description of north-western Mongolia, by Pyevtsoff, being the best work on the subject. In 1888, after the sudden death of Prjevalsky, Pyevtsoff was nominated head of the Tibet expedition, and, in company with Roborovsky and Kozloff and the geologist Bogdanovich, he explored during two years eastern Turkestan and the Gobi—the results of these explorations being now embodied in three quarto volumes edited by the Russian Geographical Society. Pyevtsoff also contributed to theoretical geodesy an important paper on the determination of latitudes from the corresponding altitudes of two stars—a most useful extension of M. Tsinger's method, which has been largely applied since by Russian explorers in Central Asia—and another on barometrical levellings.

The series of Saturday afternoon excursions of the London Geological Field Class, conducted by Prof. H. G. Seeley, F.R.S., will commence on April 26, when a visit will be paid to Erith. The excursions will be continued on each succeeding Saturday (except on Saturdays before Whitsuntide and in Coronation week) until July 12. Further particulars can be obtained from the hon. general secretary, Mr. R. Herbert Bentley, 43 Gloucester Road, Brownswood Park, N.

Dr. H. R. Mill has collected observations relating to the frost of February last from all available sources, and has published in Symons's *Meteorological Magazine* for March an interesting summary of the results, with a sketch-map which shows diagrammatically the number of days of frost in different parts of the country. With the exception of the long-continued cold of

February 1895, the recent frost was the most prolonged and severe that has been experienced in February for half a century. Dr. Mill measures the duration of the frost by the number of nights during which the temperature in the shade fell below the freezing point. In most places the cold weather set in on the 1st, and, generally speaking, lasted for three weeks, except on the sea coasts. For instance, at Torquay the period was nine days, at Eastbourne and some other places twelve days only, while in Suffolk, Yorkshire and Peebleshire the frost lasted for twenty-four days. The lowest shade temperatures were $-2°$ at Lairg (Sutherland) and 0° at Braemar on the 14th. At Camden Square the minimum was 15°·8, the only lower records there in February being 15°·4 in 1865 and 7°·3 in 1895. The mean temperature of the month appears to have been from 3° to 5° below the average in all parts of our islands. Heavy snowfalls occurred in the north and west, but in the south-east there was an almost entire absence of precipitation during the period of the frost.

THE *Scientific American* for March 8 describes and illustrates a very novel form of flying machine which has been devised by M. Henri Villard, of Paris. The machine has not yet been ried, so at present nothing can be said about its capabilities, but the inventor hopes to carry out the first trials next spring. An idea of the apparatus may be perhaps best explained by imagining a rather flat umbrella of considerable size made rigid by an exterior steel rim and wire spokes. On the stick portion of this large umbrella, and under the umbrella, are two pro-ecting arms, one carrying a screw to move the apparatus in a horizontal direction, the other a rudder for steering purposes. Still lower down on this stick, on one side of it, say near the handle of the umbrella, is the motor, and opposite it the seat for the operator. The motor has two functions, one of which is to drive the screw for obtaining the horizontal motion, and the other, which is the novel part of this form of flying machine, for rotating at a rapid speed the umbrella portion. The idea is that the rapidly rotating umbrella with the comparatively heavy rim will act like the wheel of a gyroscope, and that this will tend to keep the machine from being easily moved out of the plane of rotation. The umbrella portion, which is practically a parachute, is a large flat wheel of twenty-two feet external diameter, resembling somewhat a bicycle wheel, the rim of which is made of half-inch diameter circular steel tubing, and this is covered on its upper portion with stout cotton balloon canvas. The parachute or wheel portion is not really a true wheel, but built on the plan of a helix, so that by rapid rotation the whole apparatus can be lifted vertically; it is stated that this will absorb about four horse-power.

AN ingenious and very convenient method for finding the velocity of underground water is described by Prof. Slichter in the *Engineering News*. The method is an electrical one, and consists in determining the time taken for an electrolyte to travel along a certain length of the stream. A double row of 1¼ inch drive wells is sunk across the channel of the stream and the upstream wells are charged with a solution of an electrolyte, ammonium chloride having been found very suitable. The electrolyte flows down stream with the moving water, and its arrival at the second row of drive wells is indicated electrically. The best method of connecting up the electrical indicator is said to be the following. One pole of the battery is connected to the outer sheathing of the lower well tubes through an ammeter; the other pole is connected to the upstream tubes and also to an insulated electrode passing down the centre of the downstream tubes. A gradual rise in current marks the passage of the electrolyte down stream; when it arrives at the lower row of wells, the resistance of the circuit between the sheathing and the inner electrode is so much diminished that a sudden kick of the ammeter occurs, marking with great precision the time of arrival. The second circuit may be dispensed with, but the moment of arrival is not in that case so sharply marked. A number of preliminary tests have been made on the rate of movement of the underflow of the Arkansas River, and a more extended and systematic survey is now being undertaken.

IN a paper recently contributed to the Royal Dublin Society, Prof. Johnson, of the Royal College of Science, directs attention to the great injury done by "smut" (*Ustilago avenae*, Jens.) to the oat crop in Ireland, and as the result of two years' experience strongly recommends the use of an American fungicide, "Sar." Sar—so-called because of the ingredients, sulphur, alkali and resin, used in its preparation—consists chiefly of sodium sulphide, and to this compound the fungicidal properties are due. Sar can be made at a cost of 6*d.* to 9*d.* per pint; and one pint in 30 to 40 gallons of water will cleanse 4 bushels of seed. The grain must be soaked for 24 hours, and for ordinary farm use it would be necessary to provide a tank capable of dealing with one day's supply of seed, say 30 to 50 bushels. Smut is a widespread pest in Britain, but partly because in normal seasons it does not do serious damage, and partly because of the unsuitability of the farmer's ordinary "steep" (solution of copper sulphate) and the trouble attending the use of Jensen's "hot-water" method, few attempts have hitherto been made to deal with the fungus. Prof. Johnson's paper should secure an extended trial for sar in Wales, the west of Scotland, and other moist districts where *Ustilago avenae* is common.

FOLLOWING the example set more than a decade ago by the Government of New South Wales, the Agricultural Department of the Government of Victoria has begun the issue of a monthly journal. In the first part, dated January 1902, the scope of this publication is indicated in an introduction written by the Hon. John Morrissey, M.L.A., Minister for Agriculture. The chief function is to bring the officers of the Department into closer touch with the agricultural population. A considerable body of information is accumulated by the experts employed by Government, and it is felt that unless this information is in active circulation it will prove of little value. An annual report does not meet the farmer's requirements, for "the annual must ever be largely a review, which in daily practice is not so much wanted as the forecast, and this the journal will aim to furnish." The thirty or so articles and notes contributed to the first number by the officers of the Department are direct, practical, freely illustrated, and well calculated to assist the agriculturist. They deal with such subjects as uses of demonstration plots, registration of remounts, best types of vat for wine-making, cream-testing, and inspection of exported butter. The journal is under the editorship of Mr. H. W. Potts. It is well arranged and well printed. It promises to be of much value to the colony.

THE British Mycological Society has just issued its transactions relating to the week's fungus foray held at Exeter in September of last year, and the papers read at the evening meetings. The most successful find was *Femsjonia luteoalba*, a genus belonging to the Tremellineæ, and one up to that time unrecorded for Britain. It was found growing on oak and birch. A paper was read by Mr. B. T. P. Baker, of Cambridge, giving some results of his cultures with Saccharomyces, which were undertaken to determine the conditions regulating spore formation. The cultures were made on plaster of Paris blocks treated with various solutions. The results seem to confirm the views put forward by Heinsen that aeration is the most important condition which regulates the production of spores. The amount of food present is also another determining factor and one which reacts differently with the two species, *S. cerevisieae* and *anomalus*, with which Mr. Baker experimented.

S. cerevisieae forms spores when it is starved, but *S. anomalus*, contrary to the generally accepted ideas, gives a bigger spore yield as the amount of food is increased. Botanists who wish to obtain spores for class work or otherwise will also do well to note that cells of the yeast will only give a good supply of spores when they are about twenty-four hours old, and none at all when they are two days old or more.

PROF. MARSHALL WARD, F.R.S., has summarised for the British Mycological Society a few of the important results which he has obtained in the course of his studies on the susceptibility of different species of brome-grasses to the attacks of the rust fungus (*Puccinia dispersa*). The development of the fungus from the uredospore when taken from one species of Bromus and transferred to another species is found to differ according to the relationship of the two Bromes. If these are closely related, the fungus infects and grows rapidly, whereas a more remote species may be entirely immune from infection. By means of carefully devised apparatus, Prof. Ward has raised pure cultures of grass from sterilised seed in germ-free tubes, and has thus been able to demonstrate that seeds from infected plants are entirely free from disease, thereby proving fairly conclusively the impossibility of intra-seminal sources of infection.

A "CATALOGUE of Altitudes in Asiatic Russia and some adjacent Portions of Asia, on the Basis of Materials Published up to 1894," by Dr. K. Hikisch, appears in the *Memoirs* of the Russian Geographical Society (General Geography, vol. xxxi., 2). The catalogue contains a very valuable list of 11,629 determinations of altitudes in Asiatic Russia, as also in Russian and Chinese Turkestan, Mongolia and Manchuria, published in the same form as they were issued by the respective authors. Unfortunately there remains still an uncertainty of about 100 feet in the altitudes of the fundamental points for most determinations—Irkutsk in Siberia and Tashkend in Turkestan. An alphabetical index of all the names considerably facilitates reference to this catalogue.

MR. JOHN CADMAN has prepared a useful account of the occurrence, mode of working and treatment of the ironstones found in the North Staffordshire Coal-field (*Trans.* Inst. Mining Engineers for 1901). The blackband ironstones occur in the upper portion of the Coal-measures beneath the Etruria Marls; they overlie seams of coal, and the thickness of the coal frequently varies in inverse ratio to the thickness of the ironstone. Sometimes the ironstones assume the nature of cannel coal, and occasionally they pass into limestone. Many fossils have been found in the ironstones, and notably through the researches of Mr. John Ward, but the mollusc Anthracomya is the prevailing shell.

THE geology of the "Riukiu Curve," or of that series of islands which lies between Formosa and Kyūshū in Japan, has been dealt with by Prof. S. Yoshiwara (*Journ.* Coll. Science, Tokyo, Japan, vol. xvi. 1901). The principal rocks of the islands are of Palæozoic age, and comprise slate, sandstone, quartzite and limestone, with amphibolite and schalstein. The ancient sedimentary rocks dip steeply to the west, and are penetrated in places by masses of granite and diorite. They form a median zone in the series of islands. The inner zone in the curve is formed mainly by volcanic rocks, and the outer zone by Tertiary strata of Miocene and later stages, which contain coal-seams and are here and there rather irregularly inclined. Raised coral-reefs are found in various districts, and these are quite horizontal. The maximum elevation of the reefs is 684 feet; they exhibit a character like those now growing in adjacent seas, and they have been upheaved after a gradual depression. The formation of the curve has been explained by Prof. Kotô as due to the depression of the "East Sea" of China, which took place for the most part in the Tertiary period. The volcanic rocks appear to belong to somewhat different stages in that period and to have originated along a great fissure which is continued in the volcanoes of Kyūshū.

THE Royal Zoological Society of Ireland has published a short account of its origin and early history. The author, Dr. D. J. Cunningham, has to lament the absence of documentary evidence, or the extreme incompleteness of such evidence, as to much of the early history of the Society; but in spite of this he has managed to bring together a number of interesting facts in connection with its foundation, and also gives portraits of some of the most prominent among the founders. The Society was established in May, 1830, at a meeting presided over by the Duke of Leinster, Dr. Whitley Stokes being elected the first hon. secretary at the second meeting, held later in the same month. It is interesting to note that the eminent ornithologist Mr. N. A. Vigors, who three years later became the first hon. secretary of the London Zoological Society, took a prominent part in the organisation of the Dublin institution.

OF the five articles included in part iv. of vol. xxix. of Gegenbaur's *Morphologisches Jahrbuch*, four are devoted to mammalian anatomy. In the longest, Herr G. Ruge discusses the varieties of form displayed by the liver of the Primates. The author considers that the mammalian liver was always divided into lobes, and was never, as has been suggested, a simple organ. Some emendation is made in the nomenclature of the lobes, and the homology of the aberrant "spigelian" and "caudal" lobes worked out. In another article, Dr. E. Stromer considers the morphological importance of the foramen found at the lower end of the humerus of many mammals and likewise of the third trochanter of the femur. From its occurrence in so many of the lower types, the entepicondylar foramen, as it is called, is regarded as a primitive structure, of which the original object was to protect certain nerves and blood-vessels. It is remarkable that it should persist in the spectacled bear of the Andes, although it has disappeared in all other living members of the group. The third trochanter of the femur, on the other hand, can scarcely be regarded as primitive, seeing that it is wanting in several of the lower groups of mammals. Neither can its presence be attributed, as Gaudry suggests, to the reduction in the number of the toes, as otherwise it should not be found in the rhinoceros. Its general absence in man forbids the idea of its having any connection with the upright posture.

THE important position occupied by the science of bacteriology in the United States may be gathered from the existence of an American Society of Bacteriologists, which has already held no less than three annual meetings. The last meeting of the society's members was held at the end of last and beginning of this year in Chicago, and a recent number of *Science* contains abstracts of the papers read. A great variety of subjects was dealt with, amongst which dairy bacteriology is well represented by contributions from Mr. H. L. Russell amongst other well-known authorities in this branch of applied bacteriology. A useful paper, as emphasising the results obtained by other investigators in the same field, is contributed by Mr. Caleb A. Fuller on "Oysters and Sewage in Narragansett Bay." The author found that oysters from a bed two miles below the sewer outlet contained bacteria typical of sewage, that 30 per cent. of the oysters from a bed situated in a strong tidal current about five miles from the sewer contained *B. coli*, that 40 per cent. of the oysters from a bed in sluggish water five-and-a-quarter miles from the sewer contained *B. coli*, and that these objectionable bacilli were only absent from oysters in beds situated more than six miles from the sewer outfall. Dr. W. J. Class submits another claimant to the title of the scarlatina microbe, in the shape of a

diplococcus said to be invariably present in cases of scarlatina and found in the throat secretions, blood, scales and urine of persons suffering from scarlet fever. He has spent much labour and time in endeavouring to place the title of this *Diplococcus scarlatinae* beyond dispute. The papers submitted, judging by the abstracts supplied by Prof. Conn, were of a high order, and the existence of such a society suggests that bacteriology in this country might well be accorded a more important place amongst the sciences than it at present occupies.

THE ninth edition of Mr. Bennett H. Brough's deservedly successful "Treatise on Mine-Surveying" has been published by Messrs. C. Griffin and Co. The book has been carefully revised, and new devices and appliances of importance are described. "The chief additions," we read, "consist of notices of the use of a spring balance for maintaining steel bands at a constant tension, of Mr. Langer's method of surveying with the hanging compass in the presence of iron, of Mr. Troye's method of marking underground stations, and of Mr. Landis's method of determining the volume excavated in open workings." By keeping his book up to date in this way, Mr. Brough makes his manual most valuable to mining students and mine-agents, who regard it as an essential volume for their libraries.

THE additions to the Zoological Society's Gardens during the past week include a Brown-headed Stork-billed Kingfisher (*Pelargopsis gurial*), an Eastern Calandra Lark (*Melanocorypha bimaculata*), an Eastern Linnet (*Acanthis fringillirostris*), a Glossy Calornis (*Calornis chalybeius*), a Small-billed Mountain Thrush (*Oreocincla dauma*), a Large Pied Wagtail (*Motacilla maderaspatensis*), an Ashy Wood Swallow (*Artamus fuscus*), a Bay-backed Shrike (*Lanius vittatus*), an Indian Great Reed Warbler (*Acrocephalus stentoreus*) from British India, a Pale Rose-finch (*Rhodospiza obsoleta*) from Afghanistan, presented by Mr. E. W. Harper; three Changeable Lizards (*Calotes versicolor*) from India, presented by Mr. R. C. McLaren; four Two-banded Monitors (*Varanus salvator*) from the East Indies, a Stump-tailed Lizard (*Trachydosaurus rugosus*) from Australia, four Changeable Lizards (*Calotes versicolor*) from India, twenty-four Black-spotted Lizards (*Algiroides nigro-punctatus*) from the Borders of the Adriatic, deposited; a Tasmanian Wolf (*Thylacinus cynocephalus*) from Tasmania, purchased; two Barbary Wild Sheep (*Ovis tragelaphus*) born in the Gardens.

OUR ASTRONOMICAL COLUMN.

DISTORTION OF SUN'S DISC AT HORIZON.—Prof. W. Prinz, of the Royal Observatory of Belgium (Brussels), has obtained several large-scale photographs of the setting sun, which show most distinctly the considerable deformation of the disc when near the horizon. The instrument employed was a photoheliograph by Steinheil. A reproduction of one of the photographs accompanies the note in *Mem. della Soc. degli Spettroscopisti Italiani*, vol. xxxi. pp. 36–39. In this case the ratio of the vertical diameter to the horizontal one is as $75:84 = 0{\cdot}893$.

THE CROONIAN LECTURE.[1]

A PECULIAR interest—the parallel of that which in the plant organism belongs to chlorophyll—attaches to hæmoglobin, for, unlike any other chemical component of the animal body, in virtue of its special chemical and physical attributes, this remarkable substance may in the strictest sense be said to possess a definite and unique physiological function.

The region of the solar spectrum which the author formerly investigated was that comprised between the lines F and Q (4861—3280). The question whether oxy-hæmoglobin presents definite absorption for light of shorter wave-lengths has since been examined. Soret, whose observations were not conducted with solutions of hæmoglobin, but merely with diluted blood, observing by the aid of his fluorescent eye-piece the cadmium spark spectrum, found that diluted blood, in addition to the absorption band in the extreme violet, exhibited two additional bands. One of these, coinciding with the 12th cadmium line (3247), he considered to be probably due to hæmoglobin; the other, coinciding with the 17th cadmium line (2743), he assumed to be caused by serum albumin, his observations having previously shown that all albuminous and albuminoid bodies, with the exception of gelatin, are characterised by an absorption band in the position of the 17th cadmium line.

Employing solutions of many times crystallised oxy-hæmoglobin of great purity and of varying concentration, and with the aid of the sparks of a powerful induction coil, the author has obtained a series of photographs of the cadmium spark spectrum with and without the interposition of the solutions. The examination of these photographs shows that solutions of oxy-hæmoglobin which are sufficiently transparent to allow the ultra-violet spectrum of cadmium to be photographed present no absorption bands corresponding either to the 14th or the 17th cadmium lines. The absorption band observed by Soret in correspondence with line 14 is, therefore, not due to the blood colouring matter, but to some other organic constituent present in the blood.

Having referred to his researches communicated to the Royal Society in June 1901, and illustrated the main facts by actual demonstrations, the author discussed (1) observations on the influence of temperature on the behaviour of oxy-hæmoglobin in the magnetic field; (2) observations on the ferro-magnetism of the ferro-albuminates.

He next dealt with the question of the specific conductivity of solutions of pure oxy-hæmoglobin. After a laborious investigation on this branch of the subject, the following conclusions were arrived at:—

(1) Although solutions of oxy-hæmoglobin possess a low conductivity, this is very much higher than has been found in the previous observations of Stewart, all of which were made at 5° C.

(2) The conductivity of solutions of oxy-hæmoglobin increases rapidly with increase of temperature, and undergoes remarkable and permanent changes when the solution is kept for even short periods at any temperature above 0° C.

These results explain the impossibility of obtaining data which can be considered trustworthy concerning the *absolute specific resistance* of solutions of oxy-hæmoglobin.

Continuing the researches contained in his first communication to the Royal Society on the results of the electrolysis of oxy-hæmoglobin, the author has found that when pure solutions of oxy-hæmoglobin are subjected to electrolysis, there occurs a separation of oxy-hæmoglobin in a colloidal, but perfectly soluble form. He has worked with currents of from 12 to 24 volts, and the intensity of the electrolysing current measured by a milliampere-meter placed in the circuit has varied in different experiments between 0·1 and 3·0 milliamperes.

By employing an electrolytic cell in which the anode is separated from the kathode by an animal membrane (sheep's intestine or pig's bladder), it is seen that the first action of the current is to cause a separation of colloidal hæmoglobin in the anode cell. This colloidal hæmoglobin falls as a beautiful red cloud, leaving a perfectly colourless, supernatant liquid. On stirring it instantly dissolves.

The further action of the current is to cause a rapid and entire transfer of the colloidal hæmoglobin from the anode to the kathode cell. With an electrolytic cell, of which each compartment had a width of 5 mm. and contained 2·5 c.c. of a 1 per cent. solution of O_2Hb, complete precipitation and transfer occurs within 60 minutes.

On reversing the direction of the current by means of a communicator, the hæmoglobin returns again in the direction of the positive current into the original cell from which it started.

The author adduced evidence which proves that the precipitated colloidal, but yet perfectly soluble, hæmoglobin represents the undecomposed molecule of the blood-colouring matter.

The probable nature of the process which occurs under the influence of the current was discussed, as well as the character o.

[1] "On Certain Chemical and Physical Properties of Hæmoglobin." By Dr. Arthur Gamgee, F.R.S., Professor Emeritus of Physiology in the Owens College. Read before the Royal Society on March 13.

the process which leads to the transfer of the hæmoglobin in the direction of the positive current. This process is considered to be of the same nature as the phenomena studied by Quincke under the name of electro-endosmose.

Special attention was directed to the importance of the facts which the author has elicited in reference to the colloidal yet soluble form of oxy-hæmoglobin. It was pointed out that all which has been said with regard to oxy-hæmoglobin applies to CO-hæmoglobin.

A typical colloid in the sense of its absolute indiffusibility through animal membranes and parchment paper, oxy-hæmoglobin differs, however, from most colloids in the facility with which it crystallises. Hitherto it has been known in its crystalline condition and in solution in water. Now in its third or colloidal form the analogy with such a colloid as silicic acid is rendered complete.

The discovery of this form of hæmoglobin enables a conception to be formed of the state in which the blood colouring matter is probably contained in the blood corpuscles. It was known that the amount of hæmoglobin contained in the corpuscles is so large that in most animals at least the whole of the water of the blood would not be sufficient to dissolve it. It was perfectly obvious, therefore, that it did not exist in the corpuscles in a state of solution, and the opinion has generally been held that these contained some unknown compound of oxy-hæmoglobin with a constituent of the stroma. It seems highly probable that in the red blood corpuscle hæmoglobin may be merely present in its colloidal form.

Finally it was pointed out that the remarkable facility with which the new colloidal form of hæmoglobin traverses such permeable membranes as the animal membranes and even parchment paper, when its solutions are subjected to electrolysis, suggests to physiologists the possibility that certain of the phenomena of absorption in the animal body may be closely connected with electromotive changes in the tissues concerned.

QUANTITATIVE INVESTIGATIONS OF BIOLOGICAL PROBLEMS.

THE first part of the new publication, *Biometrika*, was noticed in these columns on December 5, 1901 (vol. lxv. p. 106). The second part, which we have now received, bears out the promise of its founders and shows that the new quantitative methods of investigating biological problems have every claim to rank as legitimate weapons of research. The present part contains five original communications and a number of miscellanea. Dr. Warren's paper on "Variation and Inheritance in the Parthenogenetic Generations of the Aphis *Hyalopterus trirhodus*" shows that variation within the family is 60 per cent. of the racial variation, that the offspring have no greater resemblance to the mother than in sexual reproduction, but that there may be a somewhat greater fraternal resemblance than among the offspring of sexual reproduction. Mr. W. P. Elderton, in a paper entitled "Tables for Testing the Goodness of Fit of Theory to Observation," provides a set of tables useful alike to physicists, biometricians and statisticians generally who want to ascertain rapidly whether the distribution of observed data, within the limits of "a sample," is in agreement with a proposed theory. Mr. Oswald Latter, as the result of measuring 243 eggs of cuckoos and comparing them with the eggs of the clutches in which they were deposited, has come to the conclusion that there is colour-matching in 50 per cent. of cases, and in certain of the remaining cases size-matching. The bearing of these results upon Prof. Newton's theory is considered, and that theory is shown to receive confirmation therefrom. The next paper, by Dr. W. R. Macdonell, has great practical interest in connection with criminal anthropology. The author has studied the index characters hitherto used in the identification of criminals, and now shows that there is a high degree of correlation between the organs selected. He indicates the best method of dealing with the measurements, and gives suggestions for calculating uncorrelated characters "which would furnish an ideal system of identification." In connection with that most important topic, the laws of inheritance in hybrids, Prof. W. F. R. Weldon gives an account of Mendel's results of crossing races of peas which differed in one or more of seven characters. To quote the abstract of this paper:—"From a study of the work of other observers, and from examination of the 'telephone' group of hybrids, the conclusion is drawn that Mendel's results do not justify any general statement concerning inheritance in cross-bred peas. A few striking cases of other cross-bred plants and animals are quoted to show that the results of crossing cannot, as Mendel and his followers suggest, be predicted from a knowledge of the characters of the two parents crossed without knowledge of the more remote ancestry."

The notes published under the miscellanea comprise one from Prof. C. B. Davenport in which he shows that in an "abnormal" species of Hydromedusæ, *Pseudoclytia pentata*, it appears that the less typical an individual the less its fertility, and irregular individuals are more sterile than those having some sort of symmetry. The typical form and symmetry thus tend to by preserved. Prof. Karl Pearson, from a comparison of the eggs of English and American house-sparrows, is enabled to warn biometricians "against drawing conclusions from types based on the 'modes' exhibited by small samples of living forms." In another note he also shows from mummy statistics furnished by Prof. Flinders Petrie that there has been a great increase in the expectation of life since the 2000 years which have elapsed from the Romano-Egyptian epoch. Out of 100 modern English alive at ten years of age, thirty-nine survive to be sixty-eight, while not nine survived out of 100 Romano-Egyptians. Prof. Pearson also contributes a note "On the Modal Value of an Organ of Character." Miss Agnes Fry writes on variation in leaves of mulberry trees, and gives illustrations of the leaves of eight trees of different ages. From this summary of its contents it will thus be seen that the new publication is fully entitled to that support which we urged in our notice of the first part.

THE KOZLOFF EXPEDITION TO TIBET.

THE last number of the *Izvestia* of the Russian Geographical Society (1901, iv.) contains a series of very interesting letters of Captain Kozloff, the head of the last Tibet expedition. They cover the most important part of his journey, from May 1900 to October 1901, during which Kozloff and his companions, Kaznakoff and Ladyghin, explored a quite unknown country, situated between the 36th and 29th degrees of latitude and 97–99° E. longitude. A preliminary map, 27 miles to the inch, illustrates these letters.

The expedition left Tsaidam in May 1900, after having organised a meteorological station at the old Tsaidam fort, Barun-tsasak (36° 5′ N. lat., 97° 30′ E. long., 8700 ft. alt.). It crossed the high border ridge, Burkhan budda, which runs N.W. to S.E., separating the high plains of Tsaidam from the high plateau of eastern Tibet, and reached the twin lakes of the upper Hoang-ho, Jarin-nor and Orin-nor, or Lakes Expedition and Russian, as they were named by Prjevalsky. The border ridge consists here of two parallel chains, the passes through which attain the respective heights of 15,700 and 15,600 feet, while separate peaks rise another 500 or 600 feet above the passes. Under the name of Amne-machin, it is continued further S.E. in the same direction, the Hoang-ho running on the high plateau at the south-western foot of the border-ridge.

The intention of Kozloff was to explore Inner Tibet and, if possible, to reach Hlassa; but as soon as they entered the territory of Hlassa, their route was barred by a military force. Yielding to the demands of the authorities, the expedition abandoned its intention of penetrating further west, and went southwards, with the intention of visiting the Chamdo (or Tsamdo) monastery; but its route was again and again barred by military detachments, so that finally Kozloff turned eastwards, under the 30th degree of latitude, and wintered on the Dza-chu, a tributary of the Mekong, thirty miles north of Chamdo. Later on, in the spring, he crossed once more the high range of mountains which, running N.W. to S.E., separates the Mekong from the Blue River, and reached this last under the 30th degree of latitude. There the expedition made the necessary preparations for the return journey, which was resumed in April 1901, exploring the Amne-machin region on the left bank of the Yang-tse, and returning eventually to the upper Hoang-ho lakes.

Having thus described a wide curve in Tibet, the Kozloff expedition explored lands totally unknown, where the three great rivers—the Hoang-ho, the Yang-tse, and the Mekong—descend from the high Tibet plateau to the lower regions of China, and which represented a real puzzle in the orography of Asia. It

now appears that the three rivers flow on the surface of the 12,000 feet high Tibet plateau, and are separated—not by fan-like radiating mountain ranges, but by ranges of mountains rising some 3000 feet above the plateau and all running parallel to each other, N.W. to S.E. In its western portion, the high plateau, deprived as it is of the rains of the monsoon region, is a dreary desert, covered with shingle; but in its south-eastern portion, the character of the plateau changes entirely. A deep erosion makes of it an alpine mountain region. Wide valleys and deep gorges alternate with stony ridges; the routes and the footpaths go down to a deep level, or lead to great relative and absolute altitudes. Regions of soft and of rough climate, of rich and extremely poor vegetation, rapidly alternate. This alpine character already appears in the basin of the Blue River, but it is still more evident in the basin of the Mekong, where the valleys are still deeper and their vegetation still more varied. Forests of fir and of a tree-like Juniperus make their appearance, as also growths of birch, wild apricots, apple trees and a variety of bushes. In the thickly wooded gorges, the expedition also found the conspicuous white Tibet pheasants (*Crossoptilon thibetanum*), the green *Ithaginis Geoffroyi*, the *Tetraophasis obscurus*, *Tetrastes Sewertzowii*, several species of blackbirds and a good number of the smaller birds of the Passeres group. On a bright clear day the forests and the meadows are full of bird-life. Small colonies of monkeys stay in close proximity to the Tangute encampments.

On June 13 the expedition reached at last the two lakes Orin-nor and Jarin-nor, whence it proceeded to Tsaidam, and then once more across the Gobi, back to Kiakhta. It appeared that everything was in order at the meteorological station, where regular observations were made for a full year. As to the collections made in Tibet, they were very rich and contained no less than 120 mammals, 600 birds, more than 600 species of plants (10,000 specimens) and about 300 specimens of rocks. Latitudes and longitudes were determined in thirteen different spots. The expedition is now back at St. Petersburg. P. K.

CATALYSIS.[1]

THE idea and name of catalytic action were introduced into science by Berzelius in 1835, apropos of Mitscherlich's work on the formation of ether. Berzelius pointed out that the action of sulphuric acid in this case was analogous to the action of dilute acids on starch, to the similar action of malt extract, to the decomposition of hydrogen peroxide by metals and oxides, and to the action of platinum on combustible mixtures of gases. According to Berzelius, catalytic force appeared to consist essentially in this, "that substances by their mere presence and not by their affinity have the power to rouse latent affinities, so that compound substances undergo reaction and a greater electrochemical neutralisation occurs." Berzelius made no attempt to explain the phenomenon; on the contrary, in a subsequent discussion with Liebig, he insisted on the great danger of attempting to explain incompletely understood phenomena by hypothetical assumptions, lest experimental investigation should thereby be hindered. Berzelius' warning was not heeded, and the neglect of it is felt to the present day.

Catalytic actions may be divided into four classes:—(1) Release in supersaturated systems. (2) Catalysis in homogeneous mixtures. (3) Heterogeneous catalysis. (4) Enzyme actions.

(1) This first division includes phenomena which may be regarded as fundamentally explained. The best-known case is the crystallisation of a supersaturated solution, for example, of Glauber's salt, by the admission of a very small trace of the solid substance with respect to which the solution is supersaturated. We notice here in the first place the characteristic disproportion between the quantity of the acting substance and the quantity of substance changed by its influence. By a particle of dust far below the limit of what is ponderable, it is possible to bring an indefinitely large quantity of supercooled solution to congelation. The smallest particle which suffices is between 10^{-10} and 10^{-12} gramme. The processes are not limited to supersaturated solutions of solids; they are applicable also to solutions of gas. In these cases a trace of a gas may cause the liberation of an entirely disproportionate amount of another gas. Then again, supersaturation is not limited to the liquid state. Vapours can be supersaturated in respect to liquids and solid bodies, and even in the case of solids, cases are known where they are supersaturated in respect to liquids, that is to say that when they are in contact with a small quantity of liquid in question they are converted into liquid. Supersaturation on the part of solid bodies in respect to the solid bodies which can be produced from them are very common. On the contrary, supersaturation of a liquid in respect to another liquid has not been observed and would be difficult to obtain.

The theory of all these phenomena is known. In all cases we have the formation of a system the stability of which is not the greatest possible under the given conditions of temperature and pressure. There are, on the contrary, other more stable conditions which are characterised by the fact that in them a new phase, that is a physically different component with other properties, makes its appearance. In the case of a supersaturated solution of Glauber's salt, this is the solid salt; in supersaturated soda-water, it is carbonic acid gas. As a rule such a new phase does not appear spontaneously if the supersaturation is not too great, and the system behaves as if it were in equilibrium; but if a small quantity of the absent phase comes in contact with the metastable system, the action is set going and the new phase increases until equilibrium is reached.

If the new phase is a solid substance, the releasing action is associated with a solid nucleus of the same composition. Isomorphous substances have also the property; other solid bodies, on the other hand, are without action. There is here opened a wide field for investigation, since isomorphous substances probably act by the formation of solid solutions, and it is to be ascertained whether solid substances which are not isomorphous with the substance concerned, but are capable of forming solid solutions with it, are active. Further, there are cases where solid bodies act without being isomorphous or without forming solid solutions. Such artificial nuclei can be prepared, for example, by allowing silicic acid to deposit in presence of a crystal and then dissolving the crystal by means of a suitable solvent. This subject has not been fully investigated, but it explains many apparent contradictions that have occurred in the investigation of this difficult subject. Whilst the nuclei in cases of supersaturation in reference to a solid phase must be of a specific nature, in the case of supersaturation with gases any gas whatever will act as a nucleus. This is in consequence of the fact that every gas dissolves without limit in every other gas, that is, forms a homogeneous mixture with it.

A given liquid can be simultaneously supersaturated with respect to different phases, for example, one can easily melt together sodium acetate and sodium thiosulphate to form a liquid, from which, by the addition of a nucleus of either salt, that salt is separated, whilst the other remains dissolved.

Supposing we had such a liquid flowing through a tube at one point of which was a nucleus of acetate and at another of thiosulphate, then each nucleus would continue to grow in its own way as the liquid circulated. We have here an example of the physicochemical possibility of certain organic processes to which Berzelius alluded, such as the formation of the most different substances in the animal body from one and the same liquid, namely the blood. If we might consider the blood as a supersaturated solution in respect to all these substances, it would be intelligible that every organ could increase its substance from one and the same liquid. It would be inadmissible to suppose that we have here a general theory of animal secretion, for the consideration only applies to heterogeneous phases.

Again, there is the question as to whether a compound which does not preexist in the liquid, but can only come into existence by the action of contained substances, is capable of exhibiting supersaturation in regard to other phases in contact with it. There are phenomena of supersaturation known to us in connection with calcium sulphate, solutions of which are so dilute that the salt must be almost entirely in the form of its ions. Since there are no ions in the solid salt there must be here a chemical change. Dilute solutions of lead salts and thiosulphates likewise show a supersaturation in respect to lead sulphide, which is formed from them by complicated chemical decomposition. Finally, the "physical development" in photography affords examples of such phenomena.

Further examples of possible physiological applications can-

[1] The phenomena of catalytic action have been the chief subject of investigation by Prof. Ostwald and his pupils during the past few years. An account of the chief results so far obtained, together with a statement of his own views of the general character of catalytic phenomena, was given by Prof. Ostwald in September last to the German Naturforscher-Versammlung at Hamburg. What is here given is a slightly abridged translation of this address.—A. S.

not be given here, but it is probable that many problems of organic life may find solution by the application of such principles. If we generalise the conditions which have been described, we see that the most essential condition is the presence of a metastable system which only passes to the more stable state by its inherent forces, after the way has been opened to it. The nucleus of the other phase is not the *cause* of the reaction in the sense that Robert Mayer uses this word, because it does not supply the free energy necessary for the process, but is only the means of starting a process which goes to completion by its own forces after it has once been started. We may now be quite clear that the same thing must hold for all other cases of contact action. It is just the want of proportionality between the quantity of the catalytically acting substance and the amount of change which makes it a necessary condition that the changes produced catalytically supply the necessary energy themselves. The recognition of this is apparent with Berzelius when he says that by such a process "a greater electrochemical neutralisation" is effected. One of the most prominent investigators of catalytic enzyme actions states that endothermic actions can never take place in this way. This is quite incorrect, for since endothermic reactions take place of themselves, that is, without catalytic influence, there is no reason for supposing that they should not take place under enzyme influence. It is, indeed, true that under this influence no reactions are possible in which there is a reduction of free (but not of total) energy. In other words, no reactions are possible under the influence of catalysts that could not take place in their absence without a breach of one of the laws of energy. The same is to be said about the view that catalysts can only have a decomposing and not a synthetic action. Organic chemistry affords many examples to the contrary. It is only necessary to refer to syntheses by the catalytic influence of potassium ethylate.

(2) Catalysis in homogeneous mixtures.

We now come to the largest and theoretically most important class of contact actions. The explanation given for the first class cannot here be applied, for while the essential thing in the first class was the appearance of a new phase, this is now excluded by definition. We get the right standpoint for regarding the new problem by adhering to the condition which has just been laid down for all systems that undergo contact action:—the system must not represent a stable condition, for such a system can undergo no change without the addition of energy. How, then, do unstable systems behave when they are homogeneous? The answer is that homogeneous unstable systems cannot exist otherwise than in a state of change. The supersaturated solution can, if the supersaturation is within certain limits, be kept unaltered for an indefinitely long time, when properly protected. A liquid, however, which without the addition of free energy can produce other soluble liquid products cannot be kept without forming these products. This change may proceed, no doubt, very slowly, so slowly that without tedious investigation specially directed to the point no change at all can be observed, but the surest basis for general conclusions that we know—the laws of energetics—demand, as a matter of fact, that the change must take place. They prescribe no numerical value to the velocity; they only demand that the velocity be not strictly zero, but that it shall have a finite value.

By these considerations we gain now for this present case the definition of a catalyst.

A catalyst is any substance which alters the velocity of a chemical reaction without appearing in the final product.

In this definition we purposely avoid expressing any view as to what is the cause of such influence. We must, indeed, take care only to state that for all catalytic actions, causes of the same kind are at work. We seek at present only a definition which will be helpful towards a scientific investigation of the question.

That the definition just given fulfils this purpose will be at once recognised, for it leads directly to inquiry into the numerical value of the acceleration or retardation, and the dependence of this on the nature and concentration of the catalysts, the temperature, the presence of other substances, &c. It is evident, and it must be insisted upon, that all attempts to propound theories for the cause of catalytic phenomena will remain useless until quantitative measurements of the kind referred to have been made.

Regarding catalysis in the sense just defined, it is an extremely common phenomenon, one, as a matter of fact, that appears wherever the velocity of chemical reaction can be measured. The well-known researches of Menschutkin furnish a capital example. He proved that for a number of different kinds of reactions, the velocity varied between very considerable limits, according to the solvent. We must regard this effect of the solvent as catalytic. We do not thereby prejudice the further question as to the actual cause; whether, for example, there is combination between the solvent and the reagents, leading to an alteration of the active masses and so to alteration of the velocity.

We may bridge over the gap between influences of this kind and others in which vanishingly small quantities of an additional substance alter the velocity to a very high degree. Hitherto only the exaggerated cases have been called catalytic, but as the difference is only quantitative a division between them is not justifiable. So far the cases which have been investigated and measured are those in which great influences are exerted by small quantities of material, but restricting ourselves even to these, the number of cases is extraordinarily great. We are especially indebted to the labours of Schönbein for an almost endless list of such reactions. Schönbein certainly did not know that he was dealing only with accelerations of slow spontaneous processes; on the contrary, he looked upon them as being initiated by catalysts. We are thus confronted with the task of subjecting the raw material of this untiring and original investigator to a quantitative revision, a labour which would engage the united activities of a whole series of workers.

I will not attempt to enumerate such cases: I will only remark that there seems to be no kind of chemical reaction which cannot be catalytically influenced, and no chemical substances, whether elements or compounds, which cannot act catalytically. Likewise the answer to the question already asked by Berzelius, as to whether there are general or specific catalysts, must be that both kinds exist. Whilst, for example, the presence of hydrogen ions accelerates most chemical reactions, so that they must be regarded as catalysts of great generality, there are, especially among the enzymes, specific catalysts which only exert their accelerating action on perfectly definite substances. The other question of Berzelius, as to whether different catalysts can produce different products from the same substance or substances and whether different possible reactions in a given system can be effected in different ways by different catalysts, must, I think, be answered in the affirmative, although no special experiments have been made in this direction.

The first theory of catalytic phenomena was set up by Liebig and for the purpose of showing that Berzelius' conception was superfluous. Liebig regarded catalysis as the direct consequence of the law of inertia. His statement is as follows:—"The cause lies in the capacity which a substance undergoing decomposition or combination, that is, in chemical activity, possesses of arousing in a body in contact with it the same chemical activity, or of making the body susceptible of the same kind of change. This capacity is best illustrated by a burning substance, by means of which similar activity is aroused in other bodies when we bring the burning one in contact with them."

Liebig has obviously not been felicitous in this explanation. His example recoils upon him, for in order to ignite the substance we do not require a burning body, but a hot one, and it is a matter of indifference whether it is hot by means of chemical reaction or from any other cause, for example an electric current. Such objections as these were raised to Liebig's view, and he found himself obliged to give his hypothesis a different form. He expressed his view in reference to sugar fermentation in the following words:—"Just as heat is capable of disturbing the statical moment in the elements of many chemical compounds, so this can happen by means of a substance of which the elements are themselves in a condition of disturbed equilibrium; the motion which its atoms possess is imparted to the atoms of the elements of sugar; they cease to persist in that state in which they form sugar and arrange themselves according to their special attractions."

This hypothesis of molecular vibrations has enjoyed grea popularity, and represents even to-day the view of many people, especially of those who have not taken part in the investigations. It has the special advantage that it cannot be disproved, since it is altogether inaccessible to a test. The scientific unfruitfulness that lies in such a "theory" was the less perceived, inasmuch as the development of the rest of chemistry was taking place in a direction where the employment of molecular hypotheses had the value of a very important scientific auxiliary

When, however, we attempt to derive from it the slightest guidance towards experimental and exploratory work, or to deduce an idea of the possible laws of catalytic actions—and this is, indeed, the only purpose of such hypotheses—we are convinced of its entire fruitlessness. That the hypothesis of molecular vibrations drove the whole matter into a blind alley is obvious from the fact that steady scientific investigation of the problem, previously prosecuted with much zeal, did not follow. For quite a long time only isolated investigators concerned themselves with describing catalytic phenomena. Schönbein himself, to whose investigations we are so much indebted for what we know of the facts, took no part in the theoretical discussions as to the causes; on the contrary, it obviously gave him pleasure to investigate phenomena for which contemporary chemistry, to which he paid little heed, could find no explanation or place of refuge.

It is possible to speak much more favourably of another view which had long before been advocated, but meanwhile had been neglected. This is the idea of *intermediate reactions*. This had its origin in the first scientific investigation of the chemical processes that take place in the lead chamber in the manufacture of sulphuric acid. Clement and Desormes, in the year 1806, in a classical research gave the explanation, still generally accepted, of the action of oxides of nitrogen in the oxidation of sulphurous acid by atmospheric oxygen. As everyone knows, this rests upon the assumption that the sulphurous acid is oxidised by higher oxides of nitrogen, which are thereby reduced to nitric oxide. This then unites again with atmospheric oxygen, and the process can begin anew. Thus a very small quantity of oxides of nitrogen serves to oxidise a large quantity of sulphurous acid. It is remarkable that at the time of the discussion between Berzelius and Liebig this case was not brought forward, and only later do we find applications of this old view to other cases where similar chemical processes are brought about. Then, however, this mode of viewing the phenomenon became more and more general, and to-day we must regard it as the oldest and most important attempt to explain certain, though not all, catalytic processes. As a rule, however, there certainly exists a weakness in this view. In confronting a catalytic phenomenon, we seek for the possible intermediate product in the formation of which the catalyst could take part, and we consider the problem essentially solved when we can fix upon such. If we succeed, indeed, in getting some of the assumed intermediate products from the materials, the view is considered to be proved. Whether such a substance is truly an intermediate product, and not merely some bye-product, is a question which is hardly raised and still less answered.

If we test the idea from our present standpoint, we find at first something contradictory in it. In order that a process can occur at all, it must be associated with the diminution of free energy. This loss depends only on the initial and final stage of the reaction, not upon its course. On the other hand, the velocity of the reaction in strictly comparable cases is proportional to this loss. Hence we should be inclined to conclude that the velocity of reaction in a given system must have the same value, whether the process is direct or indirect—whether it takes place in one leap or in several steps.

Such a conclusion would be incorrect, for besides the loss of free energy, the velocity of reaction depends upon many other factors, which are by no means all known. A well-known example is the very great influence which temperature has, an influence which counts much more than the corresponding increase of free energy. Chemical energetics also teach us that while definite generalisations may be made concerning the equilibrium of a given system, this is not the case with the actual velocity with which equilibrium is attained. There is thus no contradiction of general laws, if we assume that a certain course of reaction takes place more quickly through an intermediate substance than it does directly. Nothing can be said for, but something against, the view that this is generally the case.

Coming back now to our classical example, which indeed in other respects will be historical, we can assume that sulphurous acid is oxidised more slowly by the oxygen of the air than by the two reactions. Oxidation of sulphurous acid by nitrogen peroxide and oxidation of nitric oxide by atmospheric oxygen run concurrently, although the concentration of the intermediate products must necessarily be smaller than the concentrations which act in a direct reaction. Whilst, however, we may regard this view as scientifically founded, there is still a chief thing wanted. The velocity of the reaction concerned must be actually measured, and until this is done one can only speak of a conjecture and not of an explanation, and what is said here is true in general for the assumption of an intermediate reaction. No catalytic acceleration is explained, unless it is also shown that the intermediate reactions actually take place more rapidly than the direct reactions, under the given conditions. Up to now, no case of this kind has been satisfactorily investigated, and no such explanation actually proved for a given case. I certainly hope that this gap will not long remain, as investigations directed to this point are approaching their conclusion.

If we assume that in certain cases the correctness of the theory of intermediate products is proved (which to all appearances is the case), we have the further question, whether all catalyses will find an explanation in this way. I believe this question may certainly be answered in the negative. I believe that there are a number of cases in which such an explanation is not applicable. In particular, I see no possibility of explaining the retarding catalytic influences by the assumption of intermediate products, for if a reaction goes more slowly *via* the intermediate products than in the direct path it will take the latter, and the possibility of intermediate products has no influence on the process.

Another theory of catalysis has been put forward by Euler. Starting from the assumption that all chemical reactions are reactions of ions and that the velocity depends on the concentration of active ions, he supposes that the catalytic substance has the property of altering the concentration of the ions. In accordance with this alteration in the concentration, the velocity of the reaction must also alter.

So far as I can see, such a theory is admissible, that is to say, it would usually be possible to make the assumption without contradicting the laws of general chemistry. Whether or not ultimately contradictions would appear, cannot be foreseen at present. There appears to be one difficulty in the fact, often observed, that two catalysts acting together effect a much greater acceleration than would be calculated from the sum of their separate effects. It is not obvious how, by the simultaneous action of the two catalysts (for example, Cupriion and Ferriion), so much larger quantities of reactive ions could be formed than these can form acting apart.

One may say of this theory, then, that it might explain some catalyses, but by no means all.

A more complicated case of catalytic phenomena is found in processes where one of the substances taking part in the reaction acts also in the capacity of catalyst. Among the possibilities of this *auto-catalysis*, I will only mention the case of a reaction producing an accelerator. This occurs, for example, in one of the best-known reactions, the solution of metals in nitric acid. The nitrous acid here formed increases in a high degree the velocity of reaction of the nitric acid, whence arise the following phenomena :—If the metal is brought into pure acid, the reaction begins with extreme slowness. In the same degree as it progresses, it becomes more rapid and in the end tumultuous. When this period is passed, the process slows down and ends with a velocity converging on zero.

This stands in striking contradiction to the usual course of reactions, which begin with a maximum of velocity and, owing to the gradual consumption of active substances, become constantly slower.

Physiological analogies present themselves irresistibly at this point. We have here a typical *fever* phenomenon. Another important physiological fact can be illustrated in the same way, *habit* and *memory*. I have here two specimens of the same nitric acid, differing only in this, that in one a small piece of copper has been already dissolved. I now bring two similar pieces of copper foil into the two acids, which are at the same temperature. You see that the acid which has already once dissolved the copper has become "habituated" to the work and begins instantly and vigorously to carry it out, while the other unpractised acid does not know how to begin with the copper, and sets about its work so clumsily and so slowly that we will not wait for it.

That we are here dealing with catalysis by means of nitrous acid will be obvious when I add some sodium nitrite to the dilatory acid; the copper is now at once attacked and dissolved.

(3) Heterogeneous Catalysis.

The best-known case of heterogeneous catalysis is the action of platinum on combustible mixtures of gases. Whilst previously the chief interest centred round mixtures of hydrogen and

oxygen, it has now passed for practical reasons to the combustion of sulphur dioxide to trioxide. In this case we are concerned, no doubt, with slow reactions, although it may be admitted that, for example, in the case of electrolytic gas, no formation of water is perceptible at the ordinary temperature in the absence of a catalyst. But the regularity of the alteration of the velocity with the temperature justifies us in the opinion that after all there is a very small velocity of reaction even at the ordinary temperature. The extremely small value is in accordance with the general fact that a gas reaction takes place very slowly. This important fact appears, for example, in the experiments of Berthelot and Péan de St. Gilles. The ester formation from acid and alcohol was compared in two experiments of the same kind, in one case the substances being liquid, in the other gaseous. Even if the experiment does not permit of an exact calculation as to whether the retardation may be fully explained by the great reduction of concentration, or whether, as is more probable, it goes beyond that, it is not to the point. It is sufficient to know that by transition to the state of gas, the velocity of the reaction is reduced to about 1/1000th.

It is possible now to set up a theory of the accelerations just mentioned. If we suppose that in the gaseous system, at a given temperature, one part is replaced by a liquid or acquires a density corresponding to the liquid state, then in this part the reaction will take place proportionately more quickly, and the liquid part of the materials will be converted into the final products. If then the liquefying or condensing source is of such a nature that it goes on condensing fresh quantities of materials as fast as the old are being used, these will react quickly and the result is acceleration of the reaction. That such is the case in the action of platinum on gases is quite possible. I do not wish to assert by this representation that the catalytic action takes place in such a way, but only to point out a possibility as to how it might take place. We should then have the simplest and purest case of an accelerating intermediate reaction to which I have already referred.

As Prof. Bredig has recently told me, it is possible to represent the mechanism of such an acceleration by means of a fluid medium in which small masses of another fluid are suspended. If this suspended liquid has the property that in it the reaction of the substances present can take place more quickly than in the main mass of the liquid, the portions of the reagents residing there will be the first to undergo change. The products will diffuse into the enveloping liquid, and thus new quantities of reagents will enter, since diffusion is always at work regulating the concentration. In this way the whole quantity of the reagents will successively find a way through the suspended liquid and react there, and the result is an acceleration of the reaction.

Bredig supposes that this view may be applied to the case where a catalyst is present in a colloidal state in the liquid. As is known, Prof. Bredig and his pupils in a series of remarkable investigations have demonstrated the manifold and energetic catalytic actions which are brought about by colloidal platinum and other colloidal metals prepared by him. He also pointed out that the extremely active catalysts occurring in nature, the enzymes, occur likewise in a state of colloidal solution or suspension.

These views have no other pretension than to be views which can be brought to an experimental test. I must not omit to draw attention to the fact that it is the view of catalysts as accelerators that has made it at all possible to put forward notions which can be so tested. Let anyone try to attain the same end by means of molecular vibrations.

(4) Enzymes.

Berzelius had no doubt that the conversion of starch into sugar by means of acids was to be classed with similar conversions by means of malt extract. The same view was held by Payen and Persoz, who isolated the active substance, diastase, or at least prepared it in a concentrated form. The same view holds good for Liebig and Wöhler, who in an excellent research studied the decomposition of amygdalin under the catalytic influence of emulsin.

The later investigations of the laws of enzyme action have, in my opinion, brought to light nothing which gives ground for a fundamental distinction between the two kinds of action. On the contrary, the researches of Bredig, before mentioned, have displayed a much more thorough-going correspondence than might have been expected.

We shall look upon the enzymes, therefore, as catalysts which arise in the organs during the life of the cell and by whose action it discharges the greatest part of its duties. Not only are digestion and assimilation from beginning to end regulated by enzymes, but the fundamental life activity of most organisms, that is to say, the acquisition of the necessary chemical energy by combustion in atmospheric oxygen, takes place with the definite cooperation of enzymes, and without this would be impossible, for free oxygen is known to be a very inert substance at the temperature of organisms, and without an acceleration of the reaction, the maintenance of life would be impossible.

Berzelius had already pointed to the decisive importance that attaches to enzymes in the economy of the living being. As a matter of fact, if we put the fundamental question, "what is the physicochemical criterion of the phenomena of life?" the answer will be, "an automatically regulated production and use of chemical energy, for the animation, maintenance and increase of the living thing." We have three different means of influencing the velocity of chemical reaction—temperature, concentration and catalysis. Of these three, the first cannot be obtained for the organism at its will. We see, indeed, that in the higher animals, in which especially complicated and delicate functions are to be fulfilled, there is complete freedom from the influence of temperature, inasmuch as they provide themselves with thermostatic appliances by means of which their body temperature can be maintained constant between certain limits. Concentrations are in many ways limited by the solubility of the substances concerned. There remains only one generally applicable means of regulating the velocity of the reactions—the application of catalysts—and this without doubt admits of the solution of the problem in ideal completeness.

I must not go further into the physiological question, but I did not wish to omit pointing out the importance of catalysis in this direction. This seems to me to be at the present time especially necessary. The older chemistry, with its facts and theories, which were concerned with the preparation and the systematic and genetic relations of substances, without regard to the laws of equilibrium and change, has proved in many respects unproductive in the explanation of physiological phenomena, and it seemed as if chemistry and physics were altogether unable to contribute anything decisive towards solving the riddle of life.

On the other hand, I should like to point out with all reserve that physical and general chemistry, in the domain of which the greater portion of this question lies, is a very young science. Those of you who were present at the Naturforscher Versammlung in 1892 will remember that it first, so to speak, "came out" there like a full-grown young lady. Hitherto she has found so much to do in her own house that she has only been able occasionally to pursue her labours in other regions, but it cannot be denied that many a hand has wished to pluck the fruits without knowing what to do with them.

It is my full and repeatedly expressed opinion that by means of the later advances of chemistry there lies before physiology a development which will be in no degree less important than that which was brought about by Liebig in his time by the first systematic application of chemical science.

So far as the properties of the enzymes are concerned, these have hitherto been investigated mainly in a qualitative way. Quantitative work meets with the great difficulties which lie in the alterability of the substance, associated, as a rule, with the loss of catalytic power. The enzymes hitherto investigated show essentially the chemical properties of albumenoids, but the question of their chemical nature is by no means yet settled. I should like to express my conviction that a more thorough investigation will disclose other intermediate stages between albumenoid products with which enzyme activities have been shown to be associated and the more simple compound substances of organic chemistry. Thus, for example, the catalytic acceleration of some oxidation processes which are characteristic of hæmoglobin seems to be maintained in its non-albumenoid derivatives, especially in hæmatin, and a following out of these relations in the decomposition products of the colouring matter of the blood would be of no slight interest.

In a few cases in which the cause of the velocity of an enzyme action has been studied in such a way as to be completely free from objection, contradictory results have appeared; while some authors have found a thorough-going agreement with the simple laws which are applicable to inorganic catalysts, others have found discrepancies.

From a hitherto unpublished article which lies before me, and in which I am inclined to place great confidence, I gather as a matter of fact that the time law of enzyme actions differs from the simplest scheme of reaction velocities. This question is, however, not yet ripe for discussion.

The question of the range of substances which can be altered by a given enzyme in a certain manner (for example, hydrolysed) is likewise in the first stage of solution, and there seems to be here similar multiplicity of function to what is found in the case of other catalysts.

The beautiful investigations of E. Fischer have shown that at any rate the very slight differences which nowadays we know in chemistry as stereochemical can bring about alteration in the action of a given enzyme. As to whether this rests on the asymmetric character of the enzyme itself or on other grounds appears to me not to have been decisively ascertained.

I must hasten to a conclusion. I have set myself the task of pointing out the broad provinces of a fertile land, which only here and there shows the first beginning of systematic cultivation, but of which the fruitfulness and importance is beyond all question. Even if the land lies outside the region to which the chemistry of the past was acclimatised, still our restless science has already begun with its new implements to make the new soil fruitful. That it is not only a chemical interest that makes the work grateful I think I have shown you by examples of its physiological application. It is also evident, from the examples which we already have of the application of this auxiliary, that the scientific knowledge and investigation of catalysis must have vast consequences in technical applications. The last great triumph of German technical chemistry, the synthesis of indigo, which will revolutionise the agricultural conditions of whole countries, contains as an essential factor a new catalysis. The oxidation of naphthalene by means of sulphuric acid with speed can only be brought about in the presence of mercury. The sulphuric acid itself, it is hardly necessary to say, is prepared by a catalytic process, whether we use the old or the newer method. When we consider that the acceleration of the reaction by catalysis is achieved without consumption of energy, and so proceeds in this sense *gratis*, and that in chemical industry, as in all other, time is money, we perceive that the systematic utilisation of catalytic appliances is likely to lead to the most thorough-going changes in manufacturing processes.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

THE Government Education Bill has been the subject of much discussion since Mr. Balfour described its provisions to the House of Commons last week. Public opinion is decidedly in favour of the creation of local educational authorities, but it is felt that unless these new bodies are made responsible for elementary as well as secondary education, the main object of the Bill will be lost. As the president of the National Union of Teachers pointed out at the conference at Bristol, there would still exist in the same district "separate authorities for primary and secondary education, with their useless and unnecessary administrative expenditure, their jealous rivalries and interminable friction." The only way to end this state of things is to make each constituted local authority responsible for the whole of the educational work in its district. There must be no clause making it optional to adopt the elementary part of the measure, for in many cases this would mean that there would still be competing schools and educational agencies instead of an organised system. The members of School Boards who have a real knowledge of education would naturally be absorbed by the local authorities, and those who are more identified with sectarian and political interests would be left to find another platform for their polemics. The views of teachers in primary schools are expressed in the following resolution brought before the Bristol conference by Mr. R. Waddington:—"That conference expresses approval of the main principles of the Education Bill, 1902, under which may be created local authorities controlling and maintaining all forms of education within wide areas, and hereby records its satisfaction with the Government's desire to place our educational system on a sound basis; but is of opinion that the measure cannot become educationally effective unless the permissive clauses of the Bill relating to elementary education be struck out, and it be made compulsory upon the local authorities to take over the control of elementary as well as of higher education." If the Government decide to withdraw the optional clause the measure will meet with general approval from most educationists.

PROF. R. MELDOLA, F.R.S., has been appointed by the President of the Board of Education a member of the Teachers' Registration Council, which has just been created to consider claims to be admitted to the Register of Teachers.

THE Lord Mayor of Liverpool has issued an appeal for funds to establish a Liverpool University upon the University College of the city. To effect this, about 330,000*l*. will be required, of which there has already been promised no less than 145,000*l*. by leading citizens. The present value or possessions of the College itself amount to more than 500,000*l*.; and the additional sum of 330,000*l*. which is asked for is to complete its equipment as a university. The existing resources of the College, the endowment of chairs and lectureships, amount to 186,300*l*.; the sites acquired and buildings erected and in course of erection, 251,550*l*.: fellowships, scholarships and prizes, 32,800*l*., exclusive of value of fellowships and scholarships established by annual gifts or granted by city and county councils, the Royal Institution, the Ladies' Educational Association, the Tate trustees, and other bodies outside University College; endowments for maintenance, 20,275*l*.; and day training college hostel and endowment, 10,000*l*. The total of 500,925*l*. does not include the value of books in the library and apparatus in laboratories, nor does it take account of sums, amounting to many thousands of pounds, given to the college year by year for immediate expenditure, nor of the annual income of the affiliated schools of architecture and applied art, public health and tropical medicine. The additional lectureships to be endowed include electrotechnics, geology and chemistry, besides others in connection with commerce, engineering and medicine.

SCIENTIFIC SERIAL.

American Journal of Science, March.—The ventral integument of trilobites, by C. E. Beecher. In previous studies of trilobites the author had not thought it worth while to illustrate the character of the ventral integument, but a recent discovery by Jaekel necessitates the separate consideration of this structure. From a study of a specimen of *Ptychoparia striata*, Jaekel has deduced an entire reconstruction of the appendages and anatomy of the trilobite. An examination of well-preserved specimens of Triarthrus, several photographic reproductions of which accompany the paper, leads to the conclusion that the deductions of Jaekel are erroneous.—Igneous rocks from eastern Siberia, by Henry S. Washington. The specimens examined included a foyaite from East Cape, comendite, quartz-porphyry, rhyolite, obsidian and monzonite from Iskagan Bay.—A cosmic cycle, by Frank W. Very.—Studies of Eocene mammalia in the Marsh collection, Peabody Museum, by J. L. Wortman. The present instalment is devoted to a consideration of *Limnocyon verus*, *velox*, *medius* and *dysodus*.—An experimental method in the flow of solids and its application to the compression of a cube of plastic material, by J. R. Benton. Frames of parallel wires were cast into the centre of a cube of Wood's metal. After the cube had been distorted beyond the elastic limits in a testing machine, the fusible metal was melted off and the structure of the framework examined. The condition of the wires after varying treatment is shown in a series of diagrams.—On the occurrence of monazite in iron ore and in graphite, by O. A. Derby.—The molecular weights of some carbon compounds in concentrated solutions with carbon compounds as solvents, by C. L. Speyers.—Clarence King, by S. F. Emmons. An account of the life-work of the late Clarence King.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, March 6.—"Experimental Researches on Drawn Steel.—Part i. Magnetism and its Changes with Temperature.—Part ii. Resistivity, Elasticity and Density, and the Temperature Coefficients of Resistivity and Elasticity." By J. Reginald Ashworth. Communicated by Prof. Schuster, F.R.S.

When magnets are heated and cooled and the cyclic state is reached, the relation of intensity to temperature is expressed by the equation

$$I_t = I_0 (1 + a t),$$

and the coefficient, a, almost universally is negative. But if a magnet be constructed of pianoforte steel wire, of large enough dimension ratio, then the coefficient is positive and the magnet gains in magnetism as the temperature rises. An attempt to trace the cause of this abnormal behaviour of pianoforte steel has led to a complete experimental investigation of the temperature coefficient of a magnet. Experiments on this wire when in the commercial drawn state, in the annealed condition, and when glass hard showed that it was only in the first state that an incremental coefficient exhibited itself, and it thus appeared that the drawing was responsible for the abnormal behaviour of the pianoforte wire. Samples of such wire were then obtained representing every stage in the manufacture from the rolled rod through annealing and tempering to the utmost stage of drawing, and from experiments on them it was demonstrated that the positive coefficient was developed by moderate drawing, but that extreme drawing tended to reduce it to zero.

The intensity of residual magnetism is remarkably increased by drawing, so that at last it is 200 per cent. greater than at first.

The relation of the curves of magnetisation of a very long thin wire of drawn steel, when cold and when hot, was next traced, and is highly interesting, as the susceptibility hot is always greater than the susceptibility cold even at maximum intensity, and it is not until the demagnetising force has been applied that the curves intersect; with iron and ordinary steel, the intersection of the curves is always on the ascending path. The temperature coefficient of induced and residual magnetism was examined at a number of points on the upward and downward curve for both drawn steel and iron, and it appears that the incremental coefficient in the drawn steel is largest, and the decremental coefficient in iron is least, when the susceptibility is a maximum, and in general the coefficient varies with the susceptibility. Another interesting observation is that after partial demagnetisation, heating and cooling restore some of the lost magnetism, and even when the whole of the magnetism is removed and an inverse magnetism of small intensity is impressed by the reversed force, heating and cooling clear this out and restore some of the original magnetism. The bearing of these experiments on the construction of magnets of constant intensity is pointed out. Observations extending over several years are given on four magnets of drawn steel.

In part ii. the relation of drawing to resistivity, to Young's modulus, and to density is traced. Resistivity is diminished by moderate drawing, but extreme traction again increases it; the temperature coefficient of resistivity is affected inversely to the resistivity. Young's modulus increases with moderate drawing and sharply declines with extreme traction; its temperature coefficient behaves inversely, so that when the modulus is large the coefficient is small, and conversely.

Density increases throughout with traction to the last stage and is then 8 grams per cubic centimetre. Magnetic intensity and density seem to be closely related, varying proportionally over a considerable range, so that the ratio of magnetic moment to the mass approaches a constant.

Chemical Society, March 19.—Prof. Emerson Reynolds, V.P.R.S., in the chair.—Nitrogen chlorides containing the propionyl group, by Dr. Chattaway. A description of chloro-derivatives of propionanilide obtained by the interaction of hypochlorous acid with propionyl derivatives of aniline.—The constitution of the metallic cyanides as deduced from their synthetic interactions. The constitution of hydrogen cyanide, by Mr. J. Wade. The formation of both organic nitriles and isonitriles by the interaction of alkyl halides with metallic cyanides seems to imply that the latter may in some cases have either of the constitutions R.C⁝N and R.N:C. The author adopts an extended form of Nef's explanation for this reaction, which assumes that the metallic cyanides are really isocyanides, and that the formation of nitriles on interaction with alkyl halides only occurs where the metal is highly positive and its isocyanide capable of forming an intermediate addition compound with the alkyl halide.—The absorption spectra of metallic nitrates, i., by Prof. Hartley, F.R.S. The author has investigated the absorption spectra of various nitrates in dilute aqueous solution. A full discussion of the results will be given in a later paper.—A method of determining the ratio of distribution of a base between two acids, by Messrs Dawson and Grant. An aqueous solution of the base and the acids is shaken with an unmiscible solvent capable of extracting one of the four possible substances present in the mixture. From the amount so removed the concentration of that substance in the solution can be determined and indirectly the amount in combination.—The molecular complexity of acetic acid in chloroform solution, by Mr. H. M. Dawson. A study of the way in which acetic acid distributes itself between chloroform and water with increasing dilution leads the author to believe that a gradual dissociation of the double molecules occurs with dilution.—The existence of polyiodides in nitrobenzene solution, by Messrs. Dawson and Gawler. In studying the ratio of distribution of iodine between the two solvents nitrobenzene and aqueous solution of potassium iodine, it was found that nitrobenzene containing iodine dissolves considerable amounts of potassium iodide due to the formation of polyiodides of potassium.—Derivatives of α-aminocamphoroxime, by Dr. Lapworth and Mr. Harvey. A description of salts and other derivatives of this oxime.—Preparation of sulphamide from ammonium amidosulphite, by Prof. Divers, F.R.S., and Mr. Ogawa. When ammonium amidosulphite is slowly heated to about 70° C., it yields about 10 per cent. of sulphamide.—Hypoiodous acid, by Mr. R. L. Taylor. The author finds that the amount of hypoiodous acid formed by the interaction of iodine and mercuric oxide depends to some extent on the fineness of division of the iodine, *precipitated* iodine furnishing 44 to 52 per cent. of the possible yield, whilst *powdered* iodine gives only small amounts.—Synthesis of imino-ethers, by Dr. G. D. Lander. A description of N-aryl benzimino-ethers produced by the interaction of aromatic imide chlorides and sodium alcoholates.—Nitration of *sym.*trihalogenacetanilides, by Dr. Orton. A description of substances obtained by the action of nitric acid on *sym.*tribromacetanilide and chlordibromacetanilide.—Purpurogallin, by Messrs. A. G. Perkin and A. B. Steven. A description of various derivatives and decomposition products of this substance, obtained in oxidising pyrogallol.—Quercetazetin, by Mr. A. G. Perkin. The flowers of the African marigold *Tageteo patula* contain a crystalline yellow colouring-matter of the formula $C_{27}H_{22}O_{13}$, to which the above name was given by Latour and Magnier de la Source in 1877. Its composition is now found to be better represented by the simpler formula $C_{15}H_{10}O_8$; it furnishes like pyrone derivatives a sulphate and a potassium compound, and when fused with potash yields protocatechuic acid and an unidentified phenol.

MANCHESTER.

Literary and Philosophical Society, March 18.—Mr. Charles Bailey, president, in the chair.—Mr. J. E. King read the second and concluding part of his paper on the folk-lore of the North American Indians, from the Jesuit relations (1611 to 1637). This described funeral rites. The bodies of the dead, he said, were first buried in village cemeteries, but after eight or ten years a great "Feast of the Dead" was held, and the bones were reburied in a grave common to many villages. After the second burial, the soul went away to the village of the dead in the west. As with other savages, the burial ceremonies implied two feelings, namely, fear of the ghost and desire to maintain a bond of union with the kindred dead. Burial and cremation were said to imply different ideas as to the future of the soul after death, but this was not illustrated by Indian beliefs, for the Indians buried their dead and also believed in their continued existence in another world. They also held the doctrine of metempsychosis, as was shown in the practice of resuscitating dead chiefs by passing on their names to living representatives. The Canadian Indians had a special form of burial for children who died in infancy; so had the ancient Romans, and so had the Hindus, West Africans, and other tribes and nations. The Hindus and Maoris, however, regarded the spirit of an infant with dread. The Canadians and other nations looked upon such spirits as helpless and pitiable, and the mode of burial adopted indicated a belief in rebirth. The paper concluded with a quotation from Lescarbots, written in 1612, which anticipated the doctrine of survival in culture.—Mr. R. F. Gwyther read a paper on the conditions which determine the rate of propagation of an earth tremor.

PARIS.

Academy of Sciences, March 24.—M. Bouquet de la Grye in the chair.—On a non-suppurative form of osteomyelitis, by M. Lannelongue. Although acute osteomyelitis is ordinarily accompanied by the staphylococcus discovered by Pasteur in certain rare forms of the disease, the symptoms of which are

given in detail, this staphylococcus is always accompanied by other micro-organisms, in one case a streptococcus, in another a *Bacterium coli*, and in another a short bacillus as yet undetermined.—Remarks relating to the demonstration of the therapeutic properties of the methylarsenate of soda, by M. Armand Gautier. Remarks on a communication on this subject by M. Mouneyrat.—The extension of Lagrange's theorem to viscous liquids and the conditions at the limits, by M. P. Duhem. The theorem of Lagrange, extended to viscous liquids, is incompatible with the conditions that liquids ought to verify along solid walls.—The direct hydrogenation of the oxides of carbon in presence of various finely divided metals, by MM. Paul Sabatier and J. B. Senderens. If in the reaction between nickel, carbon monoxide and hydrogen the temperature is raised much above 250° C., a certain proportion of carbon dioxide is always found among the products, which at 380° C. may amount to as much as 10 per cent. of the whole. The effect of replacing nickel by other metals was then examined. With cobalt the reaction proceeds exactly as with nickel, without any secondary reactions. Neither platinum, palladium, iron, nor copper gives rise to any methane under similar conditions. —On a theorem of Frobenius, by M. de Séguier.—On commutative homogeneous linear differential expressions, by M. George Wallenburg.—Oscillations peculiar to a network of conductors in electrical distribution, by M. J. B. Pomey.—On forces which act on a cathode flux placed in a magnetic field, by M. H. Pellat.—Hertzian waves in storms, by M. Firmin Larroque. In examining the effect of very distant storms, it was found that the suppression of the horizontal plate in the apparatus rendered the system inert, but that the suppression of the vertical portion of the apparatus had no effect upon the sensibility of the apparatus. The electrical oscillations are therefore horizontal. If the storm was not so distant, less than 300 kilometres, the inverse effect was generally observed.—Contribution to the study of sounding pipes, by M. C. Maltézos.—The specific heat of bodies at the absolute zero, by M. Ponsot. The author deduces by thermodynamical reasoning that at the absolute zero two systems of solid bodies comprising the same elements have the same specific heat, and discusses several particular cases.—On the boiling-point of selenium and on some other pyrometric constants, by M. Daniel Berthelot. The measurements were carried out by the interference method previously described, the necessary uniformity in heating being achieved by the use of an electrically heated nickel spiral. The boiling-point of selenium was found to be 690° C., or 25° higher than that hitherto admitted.—On the thermal equivalent of dissociation and of vaporisation, and on the heat of solidification of ammonia, by M. de Forcrand.—On a monosodium acid orthophosphate, by M. H. Giran. It has been supposed from the experiments of Zettnow that the crystals which cover the sticks of commercial metaphosphoric acid were a variety of orthophosphoric acid. It is now shown that these crystals consist of a sodium salt of the composition $NaH_5(PO_4)_2$.—On sesquisodium phosphate, by M. J. B. Senderens. The sodium phosphate described as new by M. Joulie in a recent paper in the *Comptes rendus* was discovered in 1882 by MM. Filhol and Senderens.—The action of the halogen ethers on the sulphocarbonic compounds of secondary amines, by M. Marcel Delépine.—On some new compounds of methylene, by M. Marcel Descudé. In presence of zinc chloride, trioxymethylene condenses readily with acid chlorides, the products being obtained of the types $R.COO.CH_2Cl$ and $(R.CO.O)_2CH_2$. A list of new compounds prepared by this reaction is appended.—Cane sugar in the food reserves of phanerogams, by M. Em. Bourquelot. —On the digestion of the mannane of the tubercles of orchids, by M. H. Hérissey. The mannane of the tubercles of orchids can, like the albumens, be transformed into mannose by the action of soluble ferments present in the plant.—The action of sulphurous acid as an antidote against *la casse* in wines, by M. J. Laborde. It has been shown that the destructive action of the oxydase on the red colouring matter in wine, the disease known as *la casse*, can be prevented by the addition of sulphurous acid. It is here shown that the contact of sulphurous acid and the oxydase alone is not sufficient to destroy the oxydase, and that it is the oxygen of the air which appears to be the principal agent of destruction in this case.—On the geological section of the *massif* of the Simplon, by M. Maurice Lugeon.—On the fragments of pumice found on the ocean floor, by M. J. Thoulet.—On radiometry and its application to pelvimetry, by M. Th. Guilloz.

SENSE ORGANS IN THE VEGETABLE KINGDOM.

Sinnesorgane in Pflanzenreich zur Perception mechanischer Reize. Von Dr. G. Haberlandt, o.ö. Professor an der Universität Graz. Pp. viii + 163; 6 plates. (Leipzig: Engelmann, 1901.) Price 9*s*. net.

MR. HUXLEY has truly said[1] that "perhaps the most remarkable service to the philosophy of biology rendered by Mr. Darwin is the reconciliation of teleology and morphology, and the explanation of the facts of both, which his views offer." Prof. Haberlandt is a devoted adherent to the school of evolutionary teleology; one of his earliest publications (in 1877) was a study of the protective adaptations of seedlings, and the desire to understand the meaning of every detail of plant-structure is still the key to his activity. It has led him, following the footsteps of Schwendener, to specialise in what he names physiological anatomy, which might with equal propriety be termed teleological or adaptive anatomy. Haberlandt's book,[2] in which he elucidates the minuter structure of plants from this point of view, is a recognised classic and is found in every botanical library in the world. The present work will, we think, only add to his reputation as an investigator.

The title of his book, "Sense Organs in the Vegetable Kingdom," &c., would by itself suggest the school of thought to which Haberlandt belongs, and on his first page he asserts that the plants have specific forms of irritability which are completely analogous to the senses of animals. This school, which puts side by side the reflex movements of plants and animals, dates (in its modern development) from the writings of Pfeffer and Sachs in Germany, and from the publication of "The Power of Movement in Plants" in this country,[3] and is now generally accepted.

Haberlandt's book deals with the reflexes called forth by tactile stimulation, more especially with one branch of the subject, namely, the mechanism which localises and intensifies the touch. The means by which the disturbance, thus originated, is transmitted to the motor organs is for the moment of secondary importance with the author.

Haberlandt begins with the following definition:—

"Sense organs, or organs of perception, are those structural contrivances which contribute to the reception of an external stimulus, and show a more or less striking correspondence between structure and function."

According to this broad definition, the sense organ need not itself possess the quality of percipience. The essential characteristic is an arrangement for a sudden "deformation" of the ectoplasm in sense-cells. But certain plant-hairs and bristles are called sense organs, although they merely act like the vibrissæ of animals, that is to say like levers, the act of percipience occurring in the sensitive tissues in which they are imbedded. Haberlandt practically narrows his definition by applying the term *Stimulator* to the purely mechanical parts of sense organs, a terminology which seems to us of rather doubtful value, more especially as stimulators seem to graduate into sense organs in the narrower sense.

The simplest class of sense organs contains what the author calls *Fühlpapillen* or *Tactile-papillae.* These, as they occur in the stamens of Opuntia, &c., have been already described by Haberlandt in his "Physiologische Pflanzenanatomie"; the present book demonstrates the remarkable fact that tactile papillæ occur in many different organs and in widely distinct natural orders—a state of things with which we are familiar in many adaptive structures, and which never fails to interest us. The tactile papilla in Opuntia consists of a small conical projection from an epidermic cell, into which runs a promontory of protoplasm. The fact that the papilla projects above the general surface renders it liable to be touched by the visiting insects, and the thin walls of the apical half of the papilla allow deformation to result from contact. The papillæ in this instance are not, however, very sensitive to simple contact, for if the stamens are gently rubbed they curve but slightly, whereas if the filament is forcibly bent at the same time, as would be the case when an insect visited the flower, the reaction is greater. This is only one instance of the care with which Haberlandt has, throughout, distinguished the reaction due to contact that is produced by bending of the whole organ. In this case, and also in Portulaca, it seems that if the filament is merely stroked the needle slips over the papillæ without seriously affecting them, but pressure at right angles to the filament deforms the wall of the tactile papilla and also bends the filament.

In the filaments of Berberis, the tactile papilla is of still simpler structure, being formed by the convex projection of the whole outer wall of an epidermic cell. The distribution of the cells corresponds with that of the region sensitive to contact, and here in contrast to Opuntia a slight touch, which produces no bending of the filament, is sufficient to call forth the reaction. It is true that forcible bending of the filament also has an effect, but the movement produced is incomplete; it is interesting that the motor machinery should respond less to direct deformation of its own constituent cells than to a minute change of form in the cells specialised as sense organs.

The tactile cells in Berberis differ from the non-sensitive ones in being richer in protoplasm, in containing orange chromoplasts and starch grains. The exposed projecting wall of the sense cells is not thin as in Opuntia or Portulaca; the disturbance produced by contact is apparently due to a curious thinning away of the outer wall where it meets the radial walls. This hinge-like mechanism must allow a localised deformation of the ectoplasm to occur; the cell is, in fact, like a box with strong but loosely fitting hinged lid, the hinges being the region where deformation especially occurs. The same type—a bulging epidermic cell with a hinged connection to the radial walls—occurs in Abutilon in a different natural order. The irritable stamens of Helianthemum are worthy of notice, from the absence of all definite sense organs. Haberlandt assumes that the delicacy of the epidermis renders superfluous any special arrangements; and he compares the filaments to those tendrils in which histological adaptations are absent.

[1] "Life and Letters of Charles Darwin," ii. p. 201.
[2] "Physiologische Pflanzenanatomie." 1st Edit. 1884, 2nd Edit. 1896. (Leipzig: Engelmann.)
[3] The earliest popular statement of this point of view was published by the writer of this notice in NATURE, 1878, vol. xvii. pp. 390, 411, &c.

Simple tactile papillæ occur in stigma lobes of *Goldfussia anisophylla*; they are not highly sensitive, and a pressure on them sufficient to bend the lobe is required, but whether or no the deformation of the motile tissue acts as an accessory stimulus is not easily decided. In his section on irritable styles and stigmas, Haberlandt describes the curious movements of the style of Arctotis (Compositæ), which was discovered by D. Müller in 1853, but has, until recently, received too little attention. Like the filaments of Helianthemum, it has no special sense organs, and Haberlandt suspects that the reaction is called forth by the style being forcibly bent rather than irritated by touch.

In Darwin's "Fertilisation of Orchids" the mechanism by which Catasetum shoots out its pollen-masses was for the first time described. Haberlandt has now shown that in *C. Darwinianum* and *macrocarpum* the "antennæ" which receive the stimulus, and transmit an influence to the rostellum, are provided with sense organs. His drawings (especially Taf. iii. Fig. 7) fully confirm his remark that the tactile papillæ bear a striking resemblance to those on the filaments of Opuntia and Portulaca.

In an undetermined species of Catasetum a most remarkable divergence from the type occurs. Tactile papillæ are wanting, and the antenna is converted, by the development of mechanical tissues, into a vibrissa or lever; it is capable of bending near the base, and obviously functions like filaments in Dionæa,[1] where the movement of the stiff apical part deforms the percipient joint or hinge near the base.

Allied to the tactile papillæ are the *Fühl-tüpfeln* or tactile pits discovered by Pfeffer in certain tendrils, inasmuch as by their means the protoplasmic prolongations which fill the pits are brought close to the free surface, and in such a position that they are liable to deformation by contact. Haberlandt describes these structures in detail in a variety of genera, and gives drawings of several, including the cases where a relatively large crystal is included in the pit, an arrangement which must have the effect of a stone in a man's shoe in increasing the sensitiveness to contact.[2]

For the interesting account of the minute tactile pits in the tentacles of Drosera, the reader is referred to the original. The remaining sense organs described by Haberlandt may be placed together, although by the author they are subdivided into tactile hairs, tactile bristles, stimulators, &c. Their essential character has already been referred to in describing an unnamed species of Catasetum; it is the occurrence of a stiff terminal part the movement of which deforms either the base or the tissues from which it springs. A simple example occurs on the contractile stamens of *Centaurea montana*; here the sense organs consist each of a simple, strongly built hair, the movement of which acts on the thin-walled basal joint. Other organs of the same essential type have been described[3] in Aldrovanda, but here the sensitive joint is not at the base, but in the middle of the hair.

One of the most interesting points in the book is the discovery of similar organs in Mimosa and Biophytum. The sensitive lower surface of the pulvinus of *Mimosa pudica* bears a number of obliquely lying bristles, and Haberlandt finds that the familiar reaction follows a touch applied to one of these. To convince himself of the fact the observer must, it seems, select a plant not in the highest condition of irritability; with a slightly sluggish plant it is easy to convince oneself that the bristles are the most sensitive part of the surface. The bristles are of several types, of which the most interesting is described as the "cork-squeezer" pattern.

In the angle between the bristle and the surface of the pulvinus is a projecting mass of cells, which will necessarily be squeezed when pressure is applied to the end of the bristle. The same mechanical contrivance is found among the Oxalidæ on the leaves of Biophytum, the lever being in this case a stiff hair instead of a bristle. The author points out (p. 80) that the discovery of these organs throws light on the question of the biological meaning of the irritability of Mimosa. Their existence does not seem compatible with Sachs' view that the response to contact is useful as a protection against sudden violent hail- or rain-storms. On the other hand, it lends support to Pfeffer's theory that the movement of the leaf stalks serves to warn off small creeping insects, &c. In Java and Singapore, where *Mimosa pudica* is an introduced weed, Haberlandt has seen the leaves react to visitors of this type.

The book concludes with a short section on the comparison of the tactile organs of plants with those of animals, in which the interesting point is brought out that in insects the lever-like or hinged hairs bear a distinct resemblance to corresponding structures described by the author in plants.

A NEW TREATISE ON THE CALCULUS.

An Elementary Treatise on the Calculus, with Illustrations from Geometry, Mechanics and Physics. By George A. Gibson, M.A., F.R.S.E., Professor of Mathematics in the Glasgow and West of Scotland Technical College. Pp. xix + 459. (London: Macmillan and Co., Ltd., 1901.) Price 7*s.* 6*d.*

AMONG several notable characteristics possessed by this work, the most prominent appears to be the severity of its logic. In one important respect it differs also from the usual English mathematical treatise—it seems to speak to the student, warning him against too probable error and giving him advice. This is a feature which should be encouraged. The aim of the writer of a text-book should be to educate his reader, frankly recognising the imperfections of human nature, and not merely to set forth a work of unassailable art full of unimpeachable truths.

While applied mathematics is the great field for the exercise of such a method of treatment—since erroneous views on the part of students are at once more probable and more numerous in this domain than in others—the calculus is probably, in the field of pure mathematics, the subject in which a student most needs the anticipation of errors and difficulties; and the really philosophical student will find in Prof. Gibson's treatise a work which

seems to leave no difficulty unnoticed, the Scottish love of pure logic being prominent throughout.

It is not a work for the mere smatterer who aims only at learning rules and practical processes, regardless of the logical foundations; and in its various applications and illustrations it lays under contribution the sciences of electricity, magnetism and heat. The student, however, who has no knowledge of these subjects is not hindered by the introduction of them; for they can be passed over for a more convenient season, and they are used only as examples which do not belong to the essence of the treatise.

The first hundred pages (five chapters) of the book are devoted to several subjects which are generally dealt with in other treatises—such as the elements of coordinate geometry, the most prominent properties of the conic sections, and the discussion of the limiting value of $\left(1+\frac{1}{m}\right)^m$ when $m=\infty$. In these chapters, also, there is a good deal about the graphs of functions, algebraic, exponential and trigonometric. It is possible that Prof. Gibson need not have included the portion on conic sections, since students are certain to make a special study of this elsewhere.

The whole of chapter iv. is devoted to the exposition of rates and limits, and it is minutely logical and illuminating. We cannot imagine Prof. Gibson as accepting that truly wonderful measure or definition of a variable rate which we often find in works on dynamics when their authors treat of a variable velocity:

"the velocity, when variable, is measured by the distance that would be gone over in a unit of time if the velocity remained constant and equal to that which it is at the particular instant"!

It is in chapter vi. that the special subject of the treatise begins formally with the discussion of differentiation; and here Prof. Gibson adopts the good plan of associating in the mind of the student, from the outset, both the "derivative" and the function from which it comes; in other words, the student is learning his integral as well as his differential calculus, and he is exercised in the art of deducing the function which has a given one for its derivative. There is here a section specially devoted to the properties of hyperbolic functions. The names of these functions leave much to be desired, inasmuch as several of them suffer from the fatal defect of being unpronounceable. Thus, how are sinh x and tanh x to be pronounced? And does not cosh x suggest merriment? A very simple change would remove the first difficulty. If the prefix *hy* were put to each of the trigonometrical functions, all the names would be pronounceable and not too long. Thus *hysin x*, *hytan x*, &c., would at once be pronounceable and indicate the hyperbolic nature of the functions.

Prof. Gibson's paragraph (p. 157) on the conduction of heat, together with the accompanying page of exercises, is marked by his accustomed love of clearness, but it may not be appreciated by the student of pure calculus unless he happens to have studied previously comparatively advanced physics. It is, however, a good principle to keep the purely mathematical subject as much as possible in touch with physics. There is a dangerous tendency visible in some writers to overload the special subject in hand with applications and technicalities in several other subjects, with the result that much of the work is unappreciated by the student. In this respect, however, Prof. Gibson is more judicious than many other authors. The work abounds in warnings to the student against possible (and probable) errors, and the author never hesitates to give a useful collateral piece of information, which it is desirable that the student should have, whenever it can be simply and shortly conveyed—as, for instance, at p. 175, when the different ways in which a battery of a number of cells may be arranged are discussed. This would be regarded by the typical English author as quite outside the bargain which he considers himself to have made with his reader—to give him the truth, the whole truth, and nothing but the truth, with no extra useful information, advice, or warning.

There is also plenty of the graphic method of illustration in the book in dealing both with the processes of differentiation and with those of integration.

In dealing with partial differentiation (chapter xi.), the author has a few pages devoted to the elements of coordinate geometry of three dimensions, which will, probably, be found by the student who has advanced thus far to be unnecessary. The equations of thermodynamics and also Laplace's spherical harmonic equation supply appropriate applications of the subject of the chapter.

This is followed by a very good chapter on the theory of equations, in which the methods of approximate solution are well discussed, together with the reliance to be placed on successive approximations.

The successive reductions of the binomial integral $\int x^{m-1}(a+bx^n)^{\frac{p}{q}}dx$ are dealt with rather too shortly at p. 295. It is strange that such an old work as Hymers's "Integral Calculus" should have treated these integrals in such a helpful, complete, and systematic manner, and that Hymers' simple rules for reduction in any specified case should have been quite neglected or overlooked by subsequent writers.

The mechanical method of integration by Amsler's planimeter, together with the allied geometrical theorems on the displacements of a line, is given in chapter xiv. Near the end of the book there is a thorough discussion of series, their convergency, divergency, &c. The last chapter, xx., is devoted to a short discussion of linear differential equations; and it is to be hoped that this chapter will be considerably lengthened in the next edition with a good discussion of the symbolical method of integration—a subject on which we should expect Prof. Gibson's acute logic to be very illuminating.

Finally, the work seems to be exceptionally free from misprints. We notice the extraordinary letter "O" in the centre of fig. 65, p. 315, which looks like a branch of the curve, but is really the *origin* of coordinates. See a similar defect in fig. 83, p. 362; and in line 6 from the end of p. 379 the term $p^r n$ should be ${}_pr_n$.

GEORGE M. MINCHIN.

LECTURES ON ELECTRICITY AND LIGHT.

Leichtfassliche Vorlesungen über Elektrizität und Licht. By Prof. Dr. G. Jaumann. Pp. xii + 375. (Leipzig: Barth, 1902.) Price Mk. 6.

IN a book of 370 pages it is quite impossible that the subjects of magnetism, electricity and light could be treated in anything but a scrappy manner, so that we cannot expect from Prof. Jaumann anything more than a general view of the subjects treated. The book under review arose from a course of lectures at Prague for beginners at the University and teachers in the secondary schools, and is therefore of the nature of an outline to be used as a guide in study supplemented by other more technical reading. For this purpose, if there had been a good selection of references to standard treatises, the book would have been admirable; but, unfortunately, references are almost entirely absent. The author has undoubtedly made a most interesting volume and has treated the subject in a very original manner, dealing with the phenomena of magnetism, electricity and light from a physical point of view, using throughout the Faraday conception of tubes of force. The first eighty-four pages consist of an introduction dealing with stationary stream lines in the motion of a liquid to lead on to the conceptions of magnetic and electric lines of force. The analogies between liquid stream lines due to sources and sinks and vortices and lines of force due to charges and electric currents are well brought out, and considerable ingenuity is exercised in constructing cases of fluid motion to be analogous to the behaviour of lines of electric force when more than one dielectric is present in the field. It seems, however, curious to introduce, for the benefit of readers who cannot be supposed to understand lines of force, the lines of flow for a vortex filament in a steady stream as the first case of stream lines discussed. However, later on the author deals with the resultant of two sets of stream lines and shows how complicated cases can be built up out of simple cases. This might have been done at first and have led up to the more complicated and confusing cases which he presents to the reader at the very beginning. By means of a hot or cold region in the centre of a stream, he constructs stream lines which are analogous to the lines of force for a dielectric cylinder in a steady uniform electric field. The hot region is supposed to be produced by the sun shining on this part of the stream, the rest being in shadow. As a limiting case he has a region of vapour in the middle of the stream, and states in a footnote:—

"The conditions for a stationary state of flow with a region of vapour in the middle of the stream through which the water continuously flows are left undiscussed."

This part of the book is the most interesting, but it is somewhat questionable whether the method would be really of use to a student.

The electrical and magnetic parts of the book are clearly and, on the whole, well done, in spite of the limited space at the author's disposal. The elementary parts of electrostatics are very clearly and concisely explained. There are some points which are somewhat carelessly treated—for example, it is too much to say that the process of solution of zinc in sulphuric acid is completely explained by an electrolytic decomposition due to small currents set up on the zinc producing zinc oxide and setting free hydrogen, the zinc oxide then dissolving in the acid. It is difficult to see how this is a complete explanation.

The last few pages are concerned with Röntgen, Becquerel and kathode rays. The author here is rather unfortunate, as he makes several wrong statements, *e.g.* kathode rays charge bodies on which they fall frequently with a negative, but more often with a positive charge. Also Röntgen rays are stated to be probably light rays of smaller wave-length than ultra-violet rays, and kathode rays are stated to be probably longitudinal electric waves. These statements seem extraordinary in view of the Stokes-Thomson theory of Röntgen rays and the universally accepted emission nature of kathode rays.

The illustrations are good, but sometimes superfluous—for example, on p. 270 is an illustration of a dynamo attached to a steam engine, with no description whatever in the text, and the illustrations of telescope and microscope have no accompanying description.

On the whole, the book is very interesting and would prove extremely useful to students who have already been introduced to the elementary facts of the subjects.

OUR BOOK SHELF.

The Principles of Mechanics. Part i. By Frederic Slate, Professor of Physics in the University of California. Pp. x+299. (New York: The Macmillan Company; London: Macmillan and Co., Ltd., 1900.) Price 7*s.* 6*d.* net.

A Treatise on Elementary Dynamics. By H. A. Roberts, M.A. Pp. xi + 258. (London: Macmillan and Co., Ltd., 1900.) Price 4*s.* 6*d.*

AN interesting contrast can be made between these two little treatises on the methods of mathematical instruction in this country and America.

The English book is still full of elegant little calculus-dodging expedients, and no differential coefficient is allowed to appear, as it is intended for candidates for mathematical scholarships, who are still kept marking time so long over coordinate geometry as never to arrive at the calculus.

The American professor, on the other hand, addresses a class of college students of about the same age, but who have brought to their task a working knowledge of the calculus, as well as a good groundwork of experimental physics. This knowledge of experimental facts will enable the student to follow Prof. Slate's somewhat metaphysical presentation of the subject. Mr. Roberts has also incorporated the views of modern writers on the laws of motion, based mainly on Mach's "Science of Mechanics." This will make these treatises useful to students who are to become teachers in their turn; but Prof. Perry will say that they are unsuitable for the class of student he has in his mind, as the exercises and illustrations are throughout of the usual academic type, devoid of reality, or else based on microphysical conceptions.

Studien ü. d. Milchsaft v. Schleimsaft der Pflanzen. Von Prof. Dr. Hans Molisch. Pp. viii+109. (Jena: Gustav Fischer, 1901.)

PROF. MOLISCH gives a general account of the occurrence of laticiferous tissue and mucilage cells in plants, treating his subject specially from the point of view of the latex itself. He finds that the fluid is commonly acid or sometimes neutral in reaction, thus differing in this respect from protoplasm. He finds a curious form of vesiculated nucleus to be of common occurrence, and

describes the protein granules (first detected by H. Karsten), starch, oil, alkaloids and other contents in a number of examples. The protein granules are stated to arise (*e.g.* in *Cecropia*) inside special leucoplast-like structures, and elaioplasts are said to occur in the latex of croton. Of inorganic substances, calcium and magnesium are very often met with, but phosphorus, though present in the ash, is not apparently present except in organic compounds.

The mucilage cells and their contents are also discussed, and the author describes an apparently new substance, which he terms "luteofilin," as occurring extensively in monocotyledons and also in the Lobeliaceæ. A brief account of the aloin receptacles which are found in *Aloë soccotrina*, and some of the reactions and properties of their contents ends the volume.

Cast Iron: a Record of Original Research. By William J. Keep. Pp. xv + 225; with 117 illustrations. (New York: John Wiley and Sons. London: Chapman and Hall, Ltd., 1902.) Price 10*s.* 6*d.*

THIS volume possesses the distinction, which is yearly becoming less rare, of containing an account of original researches which are directly applicable to industrial work. Mr. Keep has devoted himself to the study of cast iron since 1885, and from time to time has expressed decided opinions regarding the best methods to be employed in foundries. In particular he has advocated the use of tests by which the amount of shrinkage during solidification is ascertained, his contention being that the quality of the metal to be tapped may thus be determined.

On p. v. a summary of the whole subject is given, so that a busy founder can in five minutes learn the practical results of Mr. Keep's teaching. In order to apply these results in practice, it is desirable also to read pp. 155 to 191, but the remainder of the book consists chiefly of the evidence on which the value of the recommendations rests, and is of interest only to those with a taste for science and a desire to understand what they are doing. The shrinkage test gives information mainly as to the percentage of silicon present, an addition of silicon being accompanied by a reduction in the shrinkage, and silicon, the author points out, acting through carbon, is the controlling element in cast iron.

Those founders who have not followed the course of scientific investigation on cast iron of late years would be well advised to study Mr. Keep's book, even if they do not agree with all that he says.

Test Papers in General Knowledge. By H. S. Cooke, M.A. Pp. vi + 97. (London: Macmillan and Co., Ltd., 1902). Price 1*s.* 6*d.*

THE author of this book has essayed a difficult task, and one cannot be surprised that he has achieved only a qualified success. The papers (eighty-five in number) are all short—too short, perhaps—but certainly do not lack variety. The work is intended for use in higher classes of primary schools, secondary schools and pupil teachers' "centres"; and the author's suggestion as to the use of the book is, "Each student should be provided with a copy, and a test (or more) should be given to the class one week, the answers of which should be returned the following week; this would give a fair opportunity of research in books of reference." There is much to be said in favour of such a plan. It may be doubted, however, if some of the knowledge which the students are thus set to obtain is of sufficient value to justify any expenditure of time on the attainment thereof. It is not easy to see, for example, what useful purpose is served by causing a youth to ascertain the length of time a letter would take to go from London to Moscow, or the cost of sending a parcel about two pounds weight to Winnipeg, or the price of a 100*l.* share in the Great Western Railway. Nor is much gained by knowing who wrote certain books unless something is also known of their nature, contents, and purpose. Are any of the pupils for whom the work is intended sufficiently grounded in scientific method to answer such questions as, "How did the teaching of Aristotle differ from that of Bacon?" or can any be expected to "compile (*sic*) a simple form of a Will?" It is only fair to the author to say that many questions are really admirable, *e.g.* "What results in history may be traceable to the discovery of the New World?" Scientific subjects, too, are, on the whole, well treated, and much useful knowledge must result from the efforts to answer thoroughly the questions asked. The general character of the papers, however, is hardly satisfactory from an educational point of view. Too much is made of mere knowledge and too little of the ability to use it. Hence one fears that they will ultimately prove tests of memory rather than of observation and resource, and that instead of "stimulating a many-sided *interest* in the facts of everyday life," the author will produce an irritating *curiosity* which grows on what it feeds. May we suggest a thorough revision? The book is worth it. Not only so, but in its present state there are many badly-worded questions and some few serious errors. We may attribute "in statu pupillar*ii*" and "Carmen Sylv*ia*" to careless proof reading; but the inaccuracies in the quotations in papers xi. and xxix. (to select two only) are quite unpardonable.

Class Book of Geology. By Sir Archibald Geikie. Fourth edition. Pp. xxi + 454. (London: Macmillan and Co., Ltd., 1902.) Price 5*s.*

SIR ARCHIBALD GEIKIE'S class-book of geology is likely to be one of those which will survive in the struggle for existence among the numerous handbooks of the subject which have been lately issued. There are many ways of accounting for the frequent appearance of new text-books. One of them, though perhaps not the principal one, is to be found in the varied requirements of pupils and teachers, and when an elementary work has run to a fourth edition, as in this case, we may fairly assume that it has met a want.

It is not easy to write a good text-book. This arises sometimes from the difficulty of observing a due sense of proportion all through, notwithstanding that the author is vastly more interested in some branches of the subject than in others, while sometimes it arises from the necessity of bringing before the student many subjects which are still matters of controversy, and the author has either to make positive statements in accordance with what he thinks the best supported theory or delicately to hint that doubts exist.

One reason why this class-book has been so successful is that Sir Archibald has covered all the most important parts of the subject without distracting the reader with controversy. In this he was, of course, much helped by the existence of his larger work, the "Text-Book," to which more advanced students can be referred.

The most important alterations in this edition are the introduction of descriptions and explanations of the phenomena of tectonic geology, for which his illustrations have been drawn chiefly from America, where these branches of the subject have been followed up with so much zeal and skill, and where recent travel has enabled Sir Archibald to examine the evidence and discuss the interpretation of the phenomena on the spot with his scientific friends on the other side of the Atlantic.

May he long enjoy the leisure he has so well earned, and still employ it in keeping his valuable educational and descriptive works up to date.

Transport of Molluscs by Waterfowl.

YESTERDAY (March 19) I witnessed an interesting instance of the capacity of quite small waterfowl to carry aquatic molluscs of considerable size. A pheasant-tailed Jaçaná (*Hydrophasianus chirurgus*), which was at large, with partially clipped wings, on the tank in the Museum grounds, had attached to one of its feet a fresh-water mussel well over an inch long, which remained there for about an hour and a half to my knowledge.

The Jaçaná, although quite a small bird, only about the size of a turtle-dove, nevertheless flew quite as well with this burden as without, covering as much as sixty yards at a flight, with its legs naturally extended behind.

Of course the partial clipping of its wings hindered it from rising high and going off altogether; but had it not been thus handicapped I am sure it could have transported its burden for miles if forced to leave the tank.

I have had more than one specimen of this Jaçaná in which a toe, or part of one, was missing, an accident which might possibly be due to the pinch of a bivalve behaving as described above. A fish or turtle might more probably be guilty of such amputation, although the Jaçaná's slim green toes look very like weed-stems when it is swimming, and the resemblance might be protective so long as the bird floated quietly without paddling.

I find from my notes that six years ago I observed one of some Tree-ducks (*Dendrocycna javanica*) which I was then keeping on this tank, with what appeared to be a big water-snail remaining attached to its toe for some time.

Indian Museum, Calcutta, March 20. FRANK FINN.

Preservatives in Milk.

I HAVE been astonished to learn from your English Government Blue-book about the scandalous, unnecessary and unnatural practice prevailing in England of putting drugs into milk for purposes of its preservation—a wrong and unnecessary act of adulteration. It is amazing that it should be pursued and for one moment permitted. Your highly appreciated publication will, I am certain, feel the necessity of defending nature's produce. All milk drawn from healthy cows is yielded sterile. The remedy against the use of drugs and late-refrigeration, &c., is to purify and preserve the milk in its natural sterile condition by quickly—on drawing it—aërating, cooling and refrigerating it down to the non-decomposing and non-fermenting temperature of 50° Fahrenheit or lower at the farms and rural factories before being sent off from the country, and having it conveyed, so chilled, into ordinary cold stores—the same as doubtless most of your butchers have, and with less reason—at the town dairy premises. Meat is so preserved and so conveyed, I understand, in England, and it is not nearly so susceptible to decomposition. The totally unnecessary consequences that are revealed by your recent official inquiry are scandalous. Dairy men evidently—and must constantly—find the milk they have to sell, not only in an advanced, but also dangerous state of fermentation, which, in self-interest, they can only, however, temporarily suppress by the processes of drugging, late-refrigeration and other disorganising practices, through neglect in the country of purifying and cooling the milk at once when drawn warm from the cow. There are plenty of simple portable appliances to use for the purpose, so why should not English farmers have them, and rural ice depots near railway stations for refrigeration of milk, as well as Continental, and notably American, country milk producers? Your farmers and milk distributors certainly need reform in their system, for you cannot possibly compete in quality of milk, butter or cheese with other countries where immediate purification by the practice of quick aëration and refrigeration of milk is pursued down to a non-fermenting temperature as soon as possible after being drawn from the cow. I have heard of a new method of milk preservation based on the infusion of gases (oxygen and carbonic acid) into milk. Whatever may be the merits of this new process I am not prepared to say, but if drugs are to be prohibited, this infusion of gases should be swept away with the rest of the doctoring methods of milk. By all means let the prohibition be utterly complete, and thus allow the consumer to drink nature's production and not chemical compounds. In this country (Belgium) the use of any drugs has long been prohibited, and our milk is superior and never complained about, and were drugs permitted a general protest would result. L. J. SERIN.

Mont-sur-Marchienne, Charleroi, Belgium.

[Mr. Serin does not seem to be aware of the fact that the Departmental Committee on the use of Preservatives in Food condemned the use of preservatives in milk. (See NATURE, December 5, 1901, p. 102.)—EDITOR.]

Rearrangement of Euclid Bk. I., pt. i.

As very widespread attention is being paid to the question of reform in geometrical teaching, and as a good many teachers are convinced that in this country the reform must be in the direction of a modification of Euclid's elements, I should be glad to elicit opinions as to the following rearrangement of the theorems in the first part of Book I. (to prop. 32, inclusive).

First, the theorems relating to angles made by two intersecting straight lines, viz., I. 13, 14, 15.

Then those relating to parallels, viz. 27, 28, 29, 30. Prop. 27 can be proved by superposition; for, if a transversal EF crossing two lines AB, CD makes the alternate angles equal, the portion BEFD can be exactly superposed on CFEA, so that, if AB, CD meet towards B, D, they must also meet towards C, A, which is impossible, ∴ AB, CD are parallel. I. 28 follows from I. 13; and 29, 30 from Playfair's axiom.

By taking these propositions early, we are enabled to rearrange the propositions respecting triangles in such a way that connected propositions are juxtaposed, which is of great assistance to the memory and to the growth of orderly ideas in the pupil's mind. The natural order would be to take those propositions which relate to a single triangle and then those which deal with the comparison of two triangles.

First, the fundamental theorem I. 32, with its corollaries, including I. 16, 17, and Euclid's axiom (which is the converse of 17).

Then 5, 6 with their extensions, viz. 18, 19, to which might be added the corollary that the perpendicular distance of a point from a straight line is the shortest.

Then 20, 21.

Then follow the *congruence* theorems 26, 4, 8, to which might well be added the conditions for the congruence of right-angled triangles in what would otherwise be the ambiguous case.

And lastly 24, 25, which are extensions of 4, 8 in much the same way as 18, 19 are extensions of 5, 6.

If to these are added the simple *locus* theorems regarding the locus of points equidistant from two given points, and the locus of points equidistant from two intersecting straight lines, the whole forms a well-rounded-off "First Part" of the deductive course.

The only innovation suggested here is the early introduction of the theorems relating to parallels. The effect of this is to render the course much more compact and orderly than is possible if the theory of parallels has to be approached through I. 16.

It is on the desirability (and the possibility, from the point of view of examinations) of this innovation that I earnestly desire opinions.

There is one other modification tacitly adopted in the above arrangement, and that is the cutting out of "constructions" from the deductive course. I believe this requires no defence. It is the first and greatest necessity, for any real improvement in geometrical teaching, that the course of constructions should be a parallel course to that of theorems, and not part of it.

Coopers Hill, April 2. ALFRED LODGE.

Protoplasmic Networks.

IN a presidential address delivered at Yale (*Contrib.*, Botanical Laboratory, Univ. Pennsylvania, ii., 1901, p. 183), Prof. Macfarlane announces his discovery of a "linin and chromatin" network continuous with the nuclear chromatin distributed through the protoplasm of plant cells. Certain other observations lead Prof. Marfarlane to suggest that these run from cell to cell, so that there is continuity, not only of cytoplasm, but also of the "hereditary substance."

It is now some three or four years since I discovered fibrils, hovering upon the limits of vision aided by the best oil-immersion lenses, which ran from nucleus to nucleus in the retina of vertebrates. The first hints were slowly followed up, and I have now established the fact that all the nuclei of the retina are connected together, by fibrils coming from the intra-nuclear networks, into a nuclear system; that is, into a reticulum of which the individual nuclei are the nodes.

As a student of the retina, my first interest in this nuclear system pervading the cytoplasmic framework turned upon the fact that it might supply us with the hitherto undiscovered link between the retinal nerve strands and the rods. This I have found to be the fact; the full details are described in a paper which I hope shortly to publish.

The importance of this discovery cannot, however, be confined to the retina. Not only have I succeeded in discovering similar inter-nuclear connecting fibrils in other tissues, *e.g.* in the brain, but the simple fact that in the retina they supply the paths for the nerve stimuli shows that they must lie somewhere nearer the basis of the morphology and physiology of protoplasm than we have hitherto succeeded in reaching.

In discussing the nature of this nuclear network and its bearing upon the "cell" doctrine, I have described a number of observations tending to show its relations, on the one hand, to the chromatin stored up in the nuclei, and, on the other, to the cytoplasm which forms the supporting framework of the retina. I have, further, endeavoured to show that it brings fresh light upon more than one difficult problem, for example, on the morphology of nerves and the nature of their peripheral terminations.

Several lines of argument made it almost certain to my mind that a similar nuclear network must also exist in plants, and I have little doubt but that Prof. Macfarlane's suggested continuity of the "hereditary substance" from "cell" to "cell" will ere long be demonstrable under the microscope.

I have suggested the term protomitomic as applicable to this nuclear system, that being as nearly as possible simply descriptive. The nuclear filaments, it is true, seem to supply some of the requirements of Strasburger's hypothetical kinoplastic fibrillar system. But the term kinoplasm, which I should have preferred using, has already passed into current use for structures which may have little or nothing to do with this nuclear connecting system, a preliminary announcement of which I have felt justified in making since my attention was called to Prof. Macfarlane's address. HENRY M. BERNARD.

Clapham, S.W., March 25.

Beechen Hedges on Elevated Ground.

VISITORS to Buxton, who are observant of trees, have been exercised during the winter by noticing how the smaller beech trees, where isolated, and especially the beechen hedges, where unsheltered, have maintained their foliage through the winter, contrary to the habit of deciduous trees.

The spray enclosed was plucked, this morning, from a tree about 12 ft. high, one of a number similarly clothed, bounding the western side of the pavilion grounds where exposed to the force of the storm winds, and standing at the elevation of the town, about a thousand feet above the sea; and, in the park close at hand, are long lengths of beech hedges exhibiting this appearance. In Ashwood Dale, half a mile away and well sheltered, the larger beeches are as leafless as the lime and the ash.

I see nothing in Kerner's "Natural History of Plants" to account for this departure—this tree being spoken of as constant in dropping its leaves—except the remark that the beech is most resourceful and to be regarded as a "weed" amongst trees, and calculated to oust others, where unhindered by human agency. Is this holding of the leaves, until pushed off by the growing points, to be regarded as a protective device in exceptional circumstances, and is this occurrence observable in young plants in similar elevated and exposed positions? WM. GEE.

Barlboro' Cottage, Spring Gardens, Buxton, March 31.

Meristic Variation in Trochus Zizyphinus.

ON recently examining a number of specimens of *Trochus zizyphinus* collected at Plymouth in September 1900, it was noticed that one specimen exhibited a peculiar abnormality, viz. the presence of two supernumerary eyes on the right side (Fig. 1). On the left side of the animal both cephalic tentacle and ocular peduncle were perfectly normal. The right cephalic tentacle was also normal, and the ocular peduncle of this side, though bearing three eyes, presented only a slight furrow indicating a partial division between the original eye and the two which are secondary and supernumerary (Fig. 2). Several cases of supernumerary eyes in Gasteropods have already been recorded, and in some cases (for example, *Patella*, *Littorina*) duplication of the eye is accompanied by duplication of the cephalic tentacle.

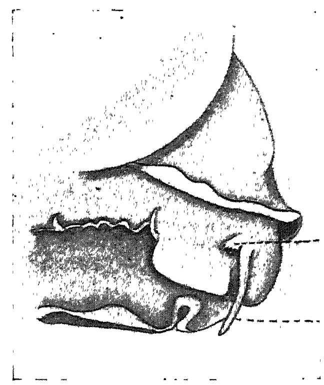

FIG. 1.—Head of abnormal specimen of *Trochus zizyphinus*, seen from the right side.

Double eyes have also been recorded in *Helix*, *Clausilia*, *Phidiana*, *Murex*, and *Sub-emarginula*[1]; in the latter, supernumerary eyes were found on both right and left sides, though in the majority of other cases they were present on one side only. It would thus appear that only double eyes have been so far recorded, and that the presence of three eyes on the right side of this abnormal specimen of Trochus is, apparently, unique. All three eyes are perfectly formed, each being provided with crystalline lens, retina, and optic nerve, thus all of them were, in all probability, functional during life.

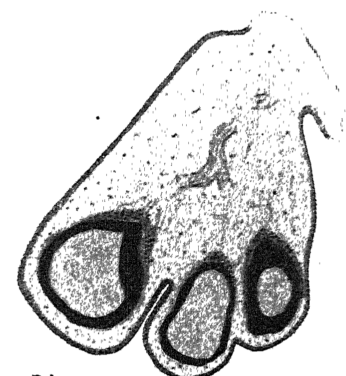

FIG. 2.—Longitudinal section of right ocular peduncle, showing the three eyes in section.

So far as can be made out from the examination of an unfortunately incomplete series of longitudinal sections through the right ocular peduncle, the innervation of the eyes is derived from a single optic nerve arising from the right cerebral ganglion. This nerve bifurcates, one branch going to the primary eye, the other branch again dividing into two, to supply the two secondary supernumerary eyes. W. B. RANDLES.

Royal College of Science, London, March 25.

Formula for the Perimeter of an Ellipse.

WILL one of your mathematical readers kindly state whether the following empirical formula gives a nearer approximation to the perimeter of an ellipse than that usually given in pocket-books of formulæ?

x and y stand for axes.

$$\text{Perimeter} = \pi\left\{\frac{x^{\frac{\log 2}{\log\pi - \log 2}} + y^{\frac{\log 2}{\log\pi - \log 2}}}{2}\right\}^{\frac{\log\pi - \log 2}{\log 2}}.$$

Molesworth's book gives the following:—

T = semi-major axis; C = semi-minor axis.

$$\text{Perimeter} = \tfrac{1}{2}\pi[\sqrt{2(T^2 + C^2)} + T + C] + 0{\cdot}2078(T - C).$$

Sounds Associated with Low Temperatures.

THERE is one place where the sounds mentioned by Mr. Cave (p. 512) can be (or used to be) heard to perfection. This is at the lower end of Beaumont Street, Oxford, where the road widens out in approaching Worcester College. The pavement and the fence adjoining it take a crescent form, and while walking on the former quite a loud metallic musical note may always be heard. The fence consists, or consisted, of boards, in front of which are iron palings, the uprights of which had a square section. SPENCER PICKERING.
Woolacombe.

Sun Pillars.

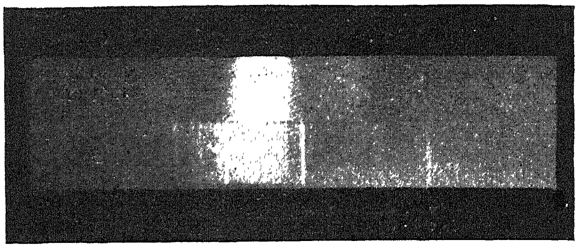
THIS evening a sun-pillar was again visible at Swindon, not so brilliant or long-lived as that which recently attracted such widespread attention, but nevertheless quite definite. I first observed it about 6.15 p.m., when the sun was a few degrees above the horizon. It was of a clear yellow colour, and extended from the dull-red sun vertically upwards. The sun set behind a bank of murky haze, and shortly after—about 6.45—the pillar had faded from view. H. B. KNOWLES.
Swindon, April 7.

LUMINOUS BACTERIA.

LUMINOUS bacteria constitute a group of organisms which under certain conditions have the power of emitting light. They occur principally, if not entirely, in sea-water. It is, however, doubtful whether they give rise to any general luminosity of the sea, such as is caused by noctiluca and other relatively high forms of marine life, although it is possible that in the tropics, where the amount of non-living nutritive material is present in sufficient quantities, that bacteria do occasionally cause a general luminosity; but the opportunities of verifying this are rare. One organism in particular, the *Photobacterium Indicum*, from its forming a surface pellicle in artificial fluid cultures, which is very luminous, may at times cause luminosity of sea-water at the surface. It is remarkable that an unicellular organism such as a bacterium should have the power of emitting light. There is no evidence of any special structure in the cell itself, and in the present state of our knowledge it is difficult to regard it as other than a result of functional activity, exactly as heat is evolved by other forms of life, as an accompaniment of the metabolism of the cell. What is, however, the exact difference between the evolution of heat by some organisms and that of light by others it is at present impossible to say. Oxygen is absorbed in both instances and carbon dioxide evolved, but there is evidently some other factor of which at present we know nothing. The fact that light and heat are manifestations of the same form of energy may apparently simplify the matter; but further consideration shows that there is a different problem to be solved in each.

We are not acquainted with any artificial method of light production, in which chemical action takes place, where light is evolved except through the medium of heat, yet in nature, by a simple cell, light is produced which is apparently unaccompanied by any invisible radiations whatever.

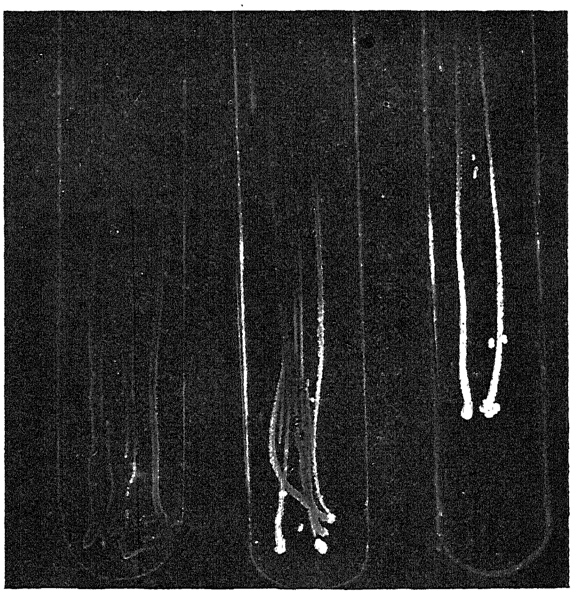
These organisms are sometimes referred to as "phosphorescent," but the term is hardly a suitable one, as the phenomenon is likely to be regarded as analogous to the emission of light by inert chemicals and minerals, or to the continued glow of vacuum tubes after an electrical



G F C

FIG. 1.—(*a*) Spectrum of luminous bacteria. (*b*) Spectrum of hydrogen for comparison.

current of high potential has been passed through them. In all marine light-producing animals, the light is not emitted continuously, but is given out at intervals in response to some stimulus or irritation. It is possible that bacteria act in the same way, but it is difficult to determine this point, as the individual organism is not sufficiently luminous to enable the observer to study it under the microscope by its own light. In fluid cultures they apparently respond to any agitation or excitation so



a *b* *c*

FIG. 2.—Cultures of different ages. (*a*) seven weeks; (*b*) three weeks; (*c*) young culture.

long as the supply of oxygen is maintained, but they can be kept in a luminous condition on fluid media if oxygen is continuously supplied in other ways, although they may remain at rest. This can be done, for instance, by allowing the wool plug, used to close the orifice of the glass vessel containing a fluid culture, to become saturated with the culture, when the plug will continue to glow for days, although the culture in the vessel may only become luminous when agitated. This points to

the agitation only resulting in the introduction of fresh oxygen and not as being a direct exciting cause.

The number of species isolated up to the present is about twenty-five, but it is more than probable that some of these are identical, or at any rate closely related.

In artificial cultivations, these organisms grow best on a medium containing a considerable percentage of a soluble chloride in addition to the nutritive material. They will grow on an ordinary peptone-beef-broth gelatine medium, but they do not all emit light, and none of them emit the maximum amount they are capable of producing. The best results are to be obtained by adding to the culture medium 2·6 per cent. of sodic chloride, ·075 per cent. of magnesia chloride, and ·3 per cent. of potassic chloride.

Either of the chlorides which occur in sea-water, if added to a nutritive medium in suitable proportions, will cause some luminosity, but the results are not so good as on the medium mentioned.

In the case of fluid nutrient media, some means must be taken to replenish the oxygen, as the amount held in solution is speedily exhausted. Either free oxygen can

FIG. 3.—Plate culture of luminous bacteria.

be allowed to bubble through the medium, in which case very brilliant cultures can be obtained, or frequent agitation can be resorted to.

The temperature at which these organisms grow is variable. Those found in northern latitudes can grow and remain luminous at 0° C., the optimum temperature being about 15°, at which reproduction is very rapid and luminosity at its maximum. Some organisms found in the tropics grow, however, at a much higher temperature, but none of them have an optimum as high as blood-heat, 37° C. Spectroscopically, the light emitted by these organisms is confined to a small portion of the visible spectrum, never extending into the ultra-violet or infra-red. Visually it only includes the green and blue, and photographically it extends very slightly further towards the violet.

Fig. 1 shows a photograph of the spectrum of this organism (*a*), with the spectrum of hydrogen beneath for reference (*b*). It will be seen that the former is continuous, and the brightest portion lies between the lines F and G. There is some extension towards the D line, but it is not well marked, and it is only with very long exposure that this becomes evident. This result has been confirmed by using a spectroscope with a quartz system, but owing to its low dispersion, the photograph here shown was regarded as more suitable for purposes of illustration.

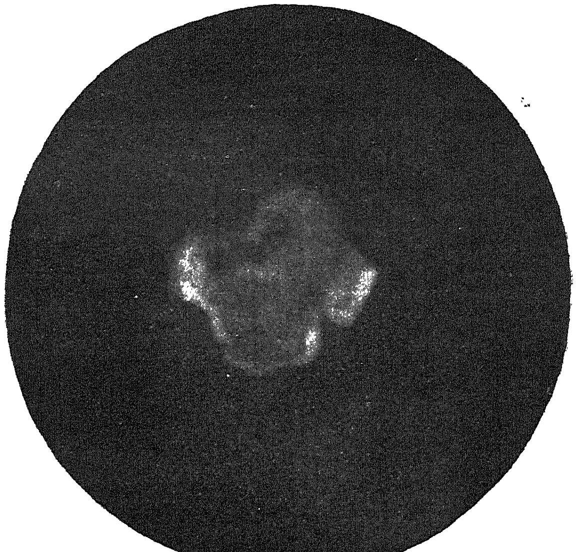


FIG. 4.—Single colony of luminous bacteria, magnified about forty-five diameters.

Figs. 2, 3, 4 and 5 are all cultures of luminous organisms, photographed entirely by their own light.

Fig. 2 is a photograph of three growths on gelatine to show the power of emitting light for long periods. The first one (*a*) is the oldest growth, some seven weeks old, in which, as always happens, the light has diminished at the centre of the streak, but is still bright at the edges, where reproduction of the organisms is still taking place. The next (*b*) is a three weeks' growth, while (*c*) is a young culture, showing that the streak is equally bright throughout.

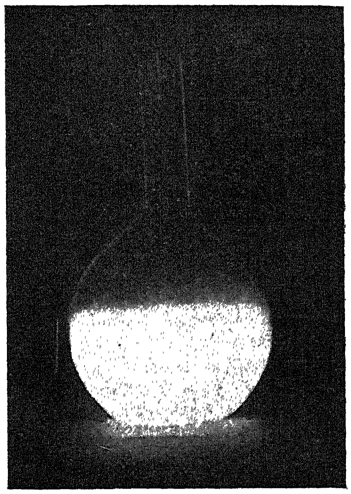

FIG. 5.—Fluid culture of luminous bacteria.

Fig. 3 is a plate cultivation one week old to show the individual colonies. Fig. 4 is a single colony magnified about forty-five diameters, showing that even in young bright growths the emission of light is greatest at the edges,

where reproduction is proceeding most actively. Fig. 5 is a large flask containing a fluid culture through which air was passed continuously while the photograph was taken.

My investigations on these organisms have been carried out at the Jenner Institute of Preventive Medicine, and I am greatly indebted to Dr. Allan Macfadyen for help and advice during the progress of the work.

J. E. BARNARD.

INTERNATIONAL COMMITTEE OF WEIGHTS AND MEASURES.

THE International Committee of Weights and Measures at Paris has just issued an account of its business and proceedings for the past year.[1] It would appear from the report of the director of the International Bureau (at Sèvres, near Paris), made to the Committee at their session in October last, that the work of the Bureau has, under the directions of the Committee, included:—Research as to the mass of a cubic decimetre of water (giving for the specific mass of water at 4° C. a value equal to 0.9999707); the study of dividing engines; investigations as to the dilatation of metals, the precise measurement of temperature, &c. The ordinary verification work of the Bureau during the past year has included:—The re-verification of metric standards (metres and kilogrammes) for the High Contracting States who have given adhesion to the Metric Convention, 1875; the verification of standards (particularly thermometers, and decimetres) for a large number of scientific and official authorities; and the installation of new bases for geodetic measurements. We are glad to see that the Committee has now been able to extend and repair its laboratories at the Pavillon de Breteuil and to perfect its arrangements for undertaking electrical measurements.

We congratulate the new secretary of the Committee, Prof. P. Blazerna (Rome); who has succeeded the late secretary the lamented Dr. A. Hirsch; on the present issue of the *Proceedings* of the Committee. Four useful appendices are attached to the volume, including:—Annexe i., on the danger of introducing normal secondary standards in the definition of metric units; a *résumé* (annexe ii.) of legislation in different countries, derived from reports presented to both Houses of Parliament by the British Foreign Office in 1900 and 1901; and particularly annexe iv., which recapitulates the decisions of the Troisième Conférence Générale held at Paris last October, as to the definition of the metric units, metre, kilogramme and litre, and the true measurements of standards of those units. The Committee also was much engaged in the discussion of these definitions, which are now published in the *Compte rendus* des Séances de la Conférence (Paris, 1901).

The members of the Committee included MM. Arndsten, D'Arrillaga, Benoit, Blazerna, De Bodola, Chaney, Cornu, Egoroff, Gautier, Hasselberg, Hepites, Von Lang, De Macedo; and M. Mendeléeff, formerly an active member of the Committee, has now been named one of the honorary members of the Committee.

Last year the annual budget of the Committee was, as in previous years, fixed at 75,000 francs; but at the meeting at Paris in October 1901 of the General Conference it was proposed that the budget should be increased to 100,000 francs annually. This proposition did not, however, receive the support of the delegate from Great Britain, but we are now glad to see that the Treasury has given its sanction for the increase in the proportionate contribution payable by this country to the Committee, based on the annual budget of 100,000 francs.

[1] "Comité International des Poids et Mesures." Procès Verbaux. Pp. 281. (Paris: Gauthier Villars, 1902) 1 vol.

SIR JOHN DONNELLY, K.C.B.

SIR JOHN DONNELLY, whose death occurred on Saturday last after a painful illness of more than six weeks, will probably be best remembered for his unceasing and devoted service in developing and administering Governmental schemes for the promotion of scientific education in this country. Soon after the end of the Crimean War, through which he served with distinction as a Lieutenant of Royal Engineers, being twice mentioned in despatches and recommended for the Victoria Cross—an honour, however, rather unjustly withheld from him—he was appointed to the charge of a detachment of Royal Engineers quartered at the South Kensington Museum. At that time this institution was but newly born, under the fostering care of the Department of Science and Art, the principal permanent chief being Sir Henry Cole, who formed the highest opinion of Donnelly's marked abilities as a clear-sighted, shrewd and wholly trustworthy young officer. About 1858-1859, Captain Donnelly succeeded the late Lord (then Dr.) Playfair as inspector for science, and a general scheme of grants applicable to the whole country was formulated and set in operation. The subjects of science towards which instruction in aid was obtainable were at first few. Among the examiners was Huxley, with whom Donnelly came to be closely associated. This close association ripened into an intimate and affectionate friendship. It is probable that to few, if any, other men did Donnelly turn with equal confidence for counsel and advice more frequently than he did to Huxley.

From a beginning of thirty-eight local science classes and schools with 1330 students in 1860 were developed the existing 2000 classes and schools attended by at least 160,000 students. Grants for practical work in laboratories at such schools were made by the Government in 1870. As early as 1867 Donnelly had a large share in putting forward a scheme for aiding local efforts to establish local scholarships and exhibitions to assist the higher instruction of students in science.

Besides the management and care of these wide-reaching operations, he assisted in reorganising the old Royal College of Chemistry in Oxford Street and the School of Mines in Jermyn Street which became in 1890 the Royal College of Science, of which the first dean was the late Prof. Huxley. In 1868 Donnelly was appointed on a commission to consider what steps should be taken to constitute a separate Department of Science and Art for Ireland, and, acting also as secretary of the commission, he drafted its report. The commission could not see its way to reporting in favour of establishing a separate Department, and up to Donnelly's retirement in July 1899 various State-aided institutions in Ireland were subject generally to his control as Secretary of the Science and Art Department, to which office he was appointed in 1884, having held the office of Director for Science from 1873.

To develop the Museum of Science as a worthy companion to the Museum of Art at South Kensington, Donnelly pressed upon the notice of his chiefs the desirability of holding a very important and successful loan exhibition of scientific instruments and apparatus, which was opened in 1874 by Her Majesty Queen Victoria in person. This led to the formation of a museum of scientific apparatus for teaching and research. For many years after the retirement of Sir Henry Cole in 1873, Donnelly was untiring in his exertions to secure Parliamentary grants for the completion and erection of properly devised permanent buildings to house the Museums of Art and Science, the component sections of which were dispersed throughout in temporary and straggling makeshift galleries and sheds. The obvious scandal that a Government could permit the existence of such a

condition gathered strength. Opponents and friends of the Department of Science and Art approached the scandal from different points of view; and in 1896 a Select Committee of the House of Commons was appointed. No witness before a Select Committee has, it is believed, ever been subjected to such a prolonged course of petty ignorant spite and vexatiousness as Sir John Donnelly was. For months he had to undergo an almost daily crossfire of idle questions. However, the main upshot of the Committee's reports was a vote by Parliament of the handsome sum of 800,000*l*. to complete the permanent science and art buildings at South Kensington, thus securing the very object to obtain which Donnelly had laboured so hard. So far as concerned the relatively unimportant malicious statements and inaccuracies which were aimed at Sir John Donnelly in passages of the Committee's reports, the Lord President and Vice-President of the Council on Education issued a minute animadverting upon them and emphasising the fact that their lordships alone were responsible for the administration of the museums; their directions had been loyally carried out by the staff and they retained the fullest confidence in Sir John Donnelly and his colleagues. There can be little doubt now that the irritation to which the Select Committee's persistent attacks put Sir John told upon his health.

Sensitive and reserved, he had an almost over-exacting sense of rectitude. He did not court society —in the conventional sense—but preferred the exclusiveness of his own circle of friends, which included many men prominent in science and art. During his yearly holidays, chiefly spent in the quiet retirement of his house amongst the pine-woods at Felday, Surrey, he frequently sketched, and season after season one or two of his painstaking etchings and water-colour paintings were to be seen at either the Royal Academy or the New Gallery.

NOTES.

IT is too early to estimate fully the effect of the magnificent endowments provided for by the will of Mr. Cecil Rhodes, but we are all able to admire the noble conception which aims at promoting a good understanding between England, Germany and the United States. It would be difficult to suggest a better means of accomplishing this than that outlined by Mr. Rhodes. Students from our colonies, the United States and Germany are to be encouraged to spend three years in the University of Oxford, where they will become familiar with our national characteristics. Nothing but good can come from the friendships which will thus be founded; and there will be a strong influence tending to bring the three nations into close relationship with one another, which will enable political and commercial questions to be discussed without the distrust usually connected with them. Rarely have endowments been made with so lofty an object; and with such an example we look hopefully to the future for other ties to bind nations together. For the present, a brief statement of the provisions of the will as regards education will be sufficient to show the scheme by which this unity of race is to be furthered. Sixty scholarships of 300*l*. a year each are to be founded for colonial students. The scholarships will be tenable at any Oxford college for three consecutive years, and twenty are to be awarded every year, this number being distributed among the various portions of the British Empire. Two scholarships of the same value are allocated to each of the fifty States and Territories of the United States of America. Moreover, in recognition of the encouragement now given in German schools to the study of English, fifteen scholarships of the value of 250*l*. a year, tenable at Oxford by German students for three years, are to be established. The will thus provides for scholarships amounting to nearly 52,000*l*. per annum, which means a capital sum of from one and a half to two millions. Some of the scholarships would have been made tenable at Edinburgh if the University there had been on a residential system; for Mr. Rhodes mentioned in his will that fifty or more students from South Africa were studying there, many of them attracted by the excellent medical school, but the want of a residential system made him refrain from establishing any scholarships in connection with the University. Oxford, like Cambridge, has such a system, and the will suggests that "it should try to extend its scope so as if possible to make its medical school at least as good as that at the University of Edinburgh." The world will now look to Oxford to increase the value of its medical school, and we shall wait with interest to see what developments are made. Mr. Rhodes's old college at Oxford, Oriel College, receives 100,000*l*., of which 40,000*l*. is for the erection of new buildings, as a fund to cover the loss to College revenue involved in the removal of houses to make room for them; 40,000*l*. to endow an increase of income of resident fellows working "for the honour and dignity of the College"; 10,000*l*. to increase the comforts of the High Table, and the remaining 10,000*l*. is to be a fund for providing for the maintenance and repair of the College buildings. A sum yielding 2000*l*. a year is set apart for the cultivation of Mr. Rhodes's property at Inyanga, and he directs in particular that irrigation should be the first object kept in view. Other objects to be borne in mind are experimental farming, forestry, market and other gardening, fruit farming, and the teaching of any of those things, and the establishment and maintenance of an agricultural college. Mr. Rhodes's gifts are both bounteous in amount and grand in intention; and they reveal a greatness of character not often found.

MR. GEORGE WILSON, whose death was announced in our last issue, was one of those who early appreciated the immense importance of applying science to manufacturing industries. The results in his case were seen in the excellence of his products and in the importance of the incidental substances which were brought to light in the course of the manufacture. In his days the importance of scientific method and its superiority to rule of thumb were not so much insisted on as they are now. Mr. Wilson was not only a chemist, but an enthusiastic horticulturist, adopting gardening at first as a recreation, and of late years making it the occupation of his life. Although he published nothing but ephemeral notes on his favourite pursuit, he constantly insisted on the necessity of applying scientific principles to practical horticulture. In a very interesting little book entitled "The Old Days of Price's Patent Candle Company," in which the history of the manufactures which resulted in such vast improvements in candle making is detailed, he says: "Laboratory training teaches careful observation and close watching, both useful in gardening, which gives a wide field for experiment. If I read the future aright ten years hence good fruit will be much more general than it is now, and for one beautiful hardy plant now common in our gardens we shall have ten." This forecast was written in 1876, and it has certainly been fulfilled, if not quite in the way that Mr. Wilson had in his mind.

FOUR zoological lectures will be delivered in the meeting-room of the Zoological Society after the general meetings on April 17, May 22, June 19 and July 17. The subjects and lecturers are:—"Flying Reptiles," by Prof. H. G. Seeley, F.R.S.; "Horses and Zebras," by Prof. J. Cossar Ewart, F.R.S.; "The Okapi," by Prof. E. Ray Lankester, F.R.S.; and "Elephants," by Mr. F. E. Beddard, F.R.S.

Arrangements have now been made for the Nature-Study Exhibition to be held at the Gardens of the Royal Botanic Society, Regent's Park, on July 23 and following days. It will be open to colleges and schools of every grade, and the exhibits will include all that bears upon nature study. Various technical instruction committees and other educational authorities have already arranged to defray the cost of the conveyance of exhibits from their respective areas, and preliminary exhibitions for the purpose of selecting the best material to send are being organised in several districts. Full particulars may be obtained on application in writing to the hon. secretary, Nature-Study Exhibition, Royal Botanic Gardens, Regent's Park, London, N.W.

The annual general meeting of the Iron and Steel Institute will be held on May 7 and 8. At the opening meeting the Bessemer gold medal for 1902 will be presented to his Excellency F. A. Krupp, of Essen. Among the subjects to be brought before the meeting are:—The nomenclature of metallography; the microstructure of hardened steel; gas from wood for use in the manufacture of steel; the physical and chemical properties of carbon in the hearth of the blast-furnace; the sulphur contents of slags and other metallurgical products; and Brinell's researches on the influence of chemical composition on the soundness of steel ingots.

Sir Samuel Wilks, Bart., F.R.S., has been elected president of the Hampstead Scientific Society in succession to the late Sir Richard Temple.

The *Times* announces the death, at Munich, of the well-known bacteriologist Prof. Hans Büchner, in the fifty-second year of his age. Prof. Büchner, who was president of the Hygienic Institute at Munich, rendered important services to science in developing the modern theory of infectious diseases. From the same source we learn of the death, at the age of eighty-seven, of M. Emile-Jean Renou, founder, in 1873, of the Saint Maur Meteorological Observatory. In 1840 he was commissioned by the Government to explore Algeria, Morocco and Tripoli, and he drew up the first geological map of Algeria.

The *Chemical News* announces that the Fifth International Congress of Applied Chemistry will be held at Berlin during the Whitsuntide holidays in 1903, under the presidency of Dr. Clemens Winkler. The House of the Imperial Parliament (Reichstag) has been placed at the disposal of the Congress, and Geheimrath Prof. Otto N. Witt has been nominated president of the organising committee, Dr. Bottinger, member of the German Parliament, acting as treasurer. A fund of about 3000*l.* has already been collected by voluntary subscriptions from societies and private individuals towards the expenses of the Congress.

We learn from *Science* that at the February meeting of the council of the American Institute of Electrical Engineers a resolution, brought forward by the committee on standardisation, in favour of the metric system was unanimously adopted. The committee's report and resolution were as follows:—(1) The metric system of weights and measures offers very great advantages by its simplicity, consistency and convenience in every-day use, as well as in all engineering calculations and computations. (2) These advantages have already been demonstrated by the universal adoption and entirely successful use of the metric system in all civilised countries except Great Britain and the United States. (3) All the electrical units in universal use, such as the volt, ampere, ohm, watt, &c., are metric units. (4) The industrial use of these electrical units would be much facilitated by the general adoption of the metric system. (5) This committee unanimously recommends the introduction of the metric system into general use in the United States at as early a date as possible without undue hardship to the industrial interests involved. (6) The committee favours such legislation by Congress as shall secure the adoption of the metric system by each department of the National Government as speedily as may be consistent with the public welfare.

In a note contributed to the *Atti dei Lincei*, xi. 4, Signor C. Somigliana shows that Lord Kelvin's method of images can be applied to the solution of the equations of elasticity, under certain conditions, for solids with plane boundaries.

The Vienna *Sitzungsberichte* contains a note by Dr. Josef von Geitler on some experiments conducted for the purpose of proving the action of kathode rays on a magnetic needle. It now appears that a source of error has been discovered in the heating of the brass tubes employed, where the rays fall on them, and the consequent production of thermoelectric currents. Unfortunately, the direction of these currents is such as to deviate the magnet in the *same* direction as it would be deviated by the rays themselves. It appears only possible by means of quantitative measurements to ascertain whether any portion of the observed effect exists over and above what is directly attributable to the source of error in question.

The "red rain" which fell in many parts of Italy and extended as far as Vienna and other central European stations on the evening of March 10, 1901, has been subsequently studied by Prof. N. Passerini, and an account of the phenomena is now given by him in the *Bolletino mensuale* of the Italian Meteorological Society. The phenomenon appears to have travelled slowly from south to north, occurring at Palermo in the night of March 9-10 and at Florence in the night of March 10-11. Prof. Passerini found that the precipitation of the earthy substance was accompanied with very little rain, and a rough analysis showed it to contain about 44 per cent. of fine sand, 32 per cent. of argillaceous matter, 12 per cent. of calcareous matter and about 10 per cent. of organic and volatile substances destroyed by calcination. The red colour was probably due to ferric hydrate. In the samples found in Pisa and elsewhere, fragments of Diatomaceæ, as well as spores, are said to have been observed. It is suggested that the material deposited in this and other so-called "rains of blood" that have occurred at different times in Italy may probably have been transported by a cyclonic disturbance, and may have had its origin in the equatorial regions of Africa or America.

The "Results of Rain, River and Evaporation Observations" made in New South Wales during 1899 have been published by Mr. H. C. Russell, Government Astronomer, and contain, as usual, valuable observations for each month and tables showing the records for various stations since 1840. The number of observing stations has risen to 1724, the observers being mostly volunteers. The year 1899 is the fifth dry year in succession, the shortage of rain for the whole colony being 21 per cent., but in a large area west of the Darling the rainfall was from 16 to 67 per cent. below the average. Six good years, 1889 to 1894, had an average of 28·61 inches of rain, and five bad ones, 1895 to 1899 inclusive, had an average of 20·49 inches. Mr. Russell remarks that only the richness of the soil and the climate save the stock under such droughts, for even a shower will often give a good growth of grass and be in time to save the stock. The crops in 1899 were to a large extent saved, except in the western districts, by the rains which fell between June and October.

The Meteorological Service of Manila, which, under the superintendence of the Observatory at that place, has for many years published valuable annual summaries, has been reorganised on the lines of the United States Weather Bureau. From the beginning of the year 1901, the new Philippine Weather Bureau has issued monthly bulletins, containing data deduced

from hourly observations, with a chronicle of the weather in English and Spanish. The bulletin also includes accounts of unusual occurrences and notes on the crops obtained from stations established throughout the Archipelago. Among the occurrences is an account of the earthquake of December 15 last. This was the strongest shock experienced since 1880, and was felt over an area almost as large as Spain. It lasted for a minute and a half, but, owing especially to the slowness of the motions, the damage caused was not great.

THE *Annuaire Météorologique* for the present year, published by the Belgian Royal Observatory, under the direction of M. A. Lancaster, has been received. The annual is full of interest, and contains many useful facts and much accurate information on meteorological matters in general. Thus, after a short summary of the more important astronomical ephemerides, we find a meteorological calendar and the second portion of the history of meteorology in Belgium, covering the period from the foundation of the Brussels Academy of Science to the first publications of the Royal Observatory. M. Lancaster brings together all the facts relating to the temperature, rainfall and wind pressure at Brussels from the year 1833 to 1900, and prints, not only the monthly means or totals, as the case may be, but the mean value for each season and for the whole year. M. Vanderlinden writes a most interesting essay on the meteorological conditions of the upper atmosphere, and describes the various means that have been and are now adopted for exploring great heights meteorologically. A number of miscellaneous tables and data follow this article, and the annual concludes with an account of the movements of the atmosphere from cloud observations made at Brussels, a *résumé* of the meteorological observations made at Uccle, near Brussels, during the year 1901, and, lastly, a description of the climate of Belgium for the year 1900.

AN illustrated account of Mr. Wilbur Wright's aëronautical experiments with gliding machines is given in the *Scientific American* for February 22. These experiments differ from those of Messrs. Lilienthal, Pilcher and Chanute in two important features, (1) the horizontal position of the operator when gliding, which is calculated to save about half a horse-power by the diminution of air-resistance, and (2) the use of a front rudder instead of one at the back of the machine. In describing one of these experiments, made with a machine of 308 square feet in a wind blowing thirteen miles an hour, the *Scientific American* states:—The machine sailed off and made an undulating flight of a little more than 300 feet. To the onlookers this flight seemed very successful, but to the operator it was known that the full power of the rudder had been required to keep the machine from either running into the ground or rising so high as to lose all headway. The experiments also showed that one of the greatest dangers in machines with horizontal tails had been overcome by the use of a front rudder, and the operators escaped from positions which had proved very dangerous to preceding experimenters. In subsequent experiments the machine with its new curvature never failed to respond promptly to even small movements of the rudder. Many glides were made whenever the conditions were favourable.

THE Report of the Felsted School Scientific Society for 1900–1 contains an interesting account, by Mr. A. A. G. Dobson, of an expedition down the Bermejo River, organised by the Messrs. Leach, the well-known sugar- and coffee-planters of the Tucuman district of Argentina.

THE most important paper in the portion of the *Proceedings* of the Philadelphia Academy for 1901, which we have just received, is one by Miss C. B. Thompson on a new nemertean worm (*Zyguepolia littoralis*) recently discovered in Massachusetts. The account, which is illustrated by five plates, occupies eighty pages.

WE have received the second (April) number of a new monthly illustrated journal, *The Country*, published by J. M. Dent and Co. and edited by Mr. H. Roberts. In addition to ordinary subjects connected with the country, inclusive of sporting, farming and gardening, this number has three articles on natural history. One of these deals with wild life in Britain, as exemplified by the black-headed gull, the second treats of the songs of birds, from the point of view of systematic classification of the species, while the third describes bird-haunts. All three are well and pleasantly written, and the first and third are attractively illustrated.

MESSRS. BLACKWOOD have sent us a copy of the first number of a new journal, the *Field Naturalist's Quarterly*, edited by Dr. G. Leighton. The part, which is illustrated with a couple of excellent full-page photographic reproductions, opens with an account of certain uncommon British sea-fishes, by Mr. F. G. Aflalo, and contains thirteen other articles, four of which deal with animals and nature in winter. That the editor does not intend to confine his purview to British subjects is indicated by an anonymous article on the fauna of New Zealand; while the wide range proposed to be embraced is made evident by one on telegony in dogs, by Prof. Ewart. The appearance of this new journal may be taken as an earnest of the reviving interest in field natural history.

WE have received parts i. and ii. of vol. lxxi. of the *Zeitschrift für wissenschaft. Zoologie*. The former is entirely devoted to an elaborate memoir on the development of the kidneys in the amniote vertebrates, by Herr K. E. Schreiner, of the Anatomical Institute of the University of Prague. Important conclusions are drawn as to the relationship of the permanent to the primitive kidneys. Among the contents of the second part is a paper on the development of the Anatidæ, as represented by the domesticated duck, by Prof. P. Mitrophanow; while another, by Herr E. Botezat, deals with the nerves in the epithelium of the tongue of mammals. In a third communication, Herr F. Urban describes a new genus and species (*Rhabdodermella nuttingi*) of calcareous sponge from Monterey Bay, California.

THE issue of an annual report by the president of the Philadelphia Academy of Sciences, which has been in abeyance since 1881, has been resumed for the past year. In this Report Mr. S. G. Dixon gives a satisfactory account of the position and prospects of the Academy, the financial resources of which were largely increased in 1900. As in most institutions of a kindred nature, the attendance at the weekly meetings has, however, sensibly decreased owing to the increasing specialisation of natural history. An enormous increase has taken place of late years in the zoological collections of the Academy, the molluscan department having since 1887, when it was regarded as the leading collection in the world, received no less than 30,000 "lots."

IN the *Quarterly Journal of Microscopical Science* for March, Mr. E. S. Goodrich publishes the first part of a paper on the structure and homology of the renal organs of Amphioxus, or, as it should properly be called, Branchiostoma. The announcement of the author's important discovery as to the identity of these organs in their segmental arrangement, function and histological structure with the nephridea (renal organs) of polychætous worms like Phyllodoce has been already made in a preliminary paper, and the evidence is now submitted to the scientific world in fuller detail, accompanied by excellent illustrations. Bearing in mind that in both cases the renal organs are furnished with so-called "solenocytes," there seems, as the

author remarks, a strong probability that they are homologous. With characteristic caution, he prefers, however, to await an investigation into their developmental history before definitely stating that this is the case. Even the provisional identification of true nephridea in the vertebrate phylum is a most important advance in our knowledge. If this be confirmed by future investigation, it is not a necessary sequence that vertebrates are derived from the polychætous worms, all that is demonstrated being that the remote common ancestor of these now widely divergent branches was of a much more specialised type than has been commonly supposed.

THE authorities at the Royal Botanic Gardens have just published, as an appendix to the *Kew Bulletin*, a list of new garden plants which have been recorded during the past year. Only a few are actually in cultivation at Kew, but of these some will be available for distribution in the regular course of exchange. In the case of the remainder, reference is given, where possible, to the individual in whose garden or collection the plant was first brought to notice. One of the objects in publishing this list is to endeavour to ensure a uniform and correct naming of new plants.

MR. J. H. MAIDEN, in an extract from the *Agricultural Gazette* of New South Wales, directs attention to the practice adopted by the Australian aborigines of obtaining water from the roots of various plants in arid districts. The trees tapped for this purpose were species of Eucalyptus known as Mallee, and Hakea or Needlebush. Also some Casuarinas were known by the natives to store up water in their stems. The usual method of treating the roots was to cut them up into pieces about nine inches long; these might receive a preliminary chew, or without being subjected to that stimulus would be set on end in order to pour out their stock of water.

THE coal resources of India formed the subject of a paper lately read by Prof. W. R. Dunstan before the Society of Arts (*Journal*, March 21). He points out that India possesses a practically inexhaustible supply of coal, mainly of permo-Triassic age, and occupying an area estimated at about 35,000 square miles. The industry of coal-mining is at present in its infancy. During the year 1900 a little more than six million tons were produced, mainly from Bengal. The principal coalfields in that province are estimated to contain 136 million tons of coal. Excellent steam and coking coal occur in Bengal and also in Assam.

A SKETCH of the geology of the north-east coast of Labrador has been contributed by Mr. Reginald A. Daly (*Bull.* Mus. Comp. Zoology, Harvard Coll., vol. xxxviii., 1902). The foundation rocks of this coast consist mainly of a crystalline complex of schists and gneisses with intruded masses and dykes of granite, diorite and gabbro, with also slates and sandstones perhaps of Cambrian age. The general strike of the rocks, whether of cleavage or stratification, coincides with the trend of the coast; and in discussing this subject the author throws out the suggestion that the great Bank of Newfoundland may be a submerged mountain-plateau at the intersection of the Labrador and Appalachian structural axes. Attention was, however, mainly given to the glacial phenomena, to the general direction of ice-movements, the "lunoid furrows" described by Packard, and the post-Glacial movements as proved by raised beaches. The ice-movement at all elevations, both in the valleys and on the hill-tops, was found to have been outward from the central part of the peninsula. The "lunoid furrows" are crescent-shaped depressions five to fourteen inches broad by three to nine inches long, and about an inch deep vertically in the rock. Mr. Daly considers that they originate from the tension or shearing stress set up in the bed-rock by boulders dragged along beneath the ice, and that the actual hollows are due to the action of frost in post-Glacial times prizing up the fragments of disturbed rock. The limit of glaciation was about 2100 feet above the sea, so that the higher massifs formed nunataks overlooking the Pleistocene ice-sheet.

THE *Journal* of the Franklin Institute contains a long and elaborate paper on the Alasko-Canadian frontier, by Mr. Thomas Willing Balch. The historical evidence is carefully analysed, and there are reproductions of a number of old maps. The author concludes that the evidence shows overwhelmingly that the United States are entitled to an unbroken strip of land on the continent from Mount St. Elias down to the Portland Channel, and believes that they should never consent to refer the matter to arbitration.

WE have received from the author a copy of a pamphlet entitled "A Sketch of the Subject of Map Projections," by Major C. F. Close, R.E. A list of selected projections is given and a short explanation of the formulæ used in constructing each, also a list of examples and books of reference. The paper, which might well be expanded into the much-needed English text-book on the subject, will be extremely useful to anyone dealing with map projections. We note that the references contain no mention of the works of Tissot, Hammer or Zöppritz.

SEVERAL popular and instructive articles on scientific topics appear in this month's magazines. The frontispiece in *Pearson's Magazine* is a reproduction of a photograph of the head of a cobra, taken when the snake's head was only a yard away from the camera. Mr. S. S. Buckman describes and illustrates some characters and actions of babies similar to those exhibited by monkeys and suggesting a common origin. Dr. C. Brown gives a number of striking pictures of fossils of various kinds, and indicates the lessons taught by them. Stages in the opening of leaves of several plants are dealt with by Mr. G. Clarke Nuttall, and are pleasingly illustrated. A number of curves drawn with a compound pendulum accompany a description by Mr. A. Williams. In the *Royal Magazine*, Mr. W. M. Webb writes an account of a caterpillar farm at Scarborough, where moths and butterflies are reared as a business. The *Sunday Magazine* has several photo-micrographs of parts of caterpillars; and a number of "minute marvels of nature" are illustrated in *Good Words*, from photo-micrographs by Mr. J. J. Ward.

THE American Society for Plant Morphology and Physiology held their annual meeting at Columbia University under the presidency of Dr. Erwin F. Smith, of the Department of Agriculture. The president, besides delivering his address on plant pathology, presented a paper dealing with the destruction of cell walls by bacteria. Leaves of the turnip were inoculated with the bacterium *Pseudomonas campestris.* The disease appeared on the leaves and passed down to the root. Sections of the root showed the bacterial masses in the vessels and adjacent parenchyma. The bacteria grow in between the cells, dissolve first the middle lamella and then the rest of the cell walls, and finally occupy large cavities which have been formed by the destruction of large portions of tissue. Dr. C. O. Townsend described another bacterial disease occurring generally on the bulbs, sometimes on the roots or leaves of the Calla lily. At the same meeting, Dr. Harshberger suggested several lines of research which might be undertaken in the West Indies, and proposed that, owing to the suspicious nature of the Tahitians, a steamer should be fitted up as a research laboratory. Prof. Ganong discussed the teaching of plant physiology to large elementary classes. Dr. Margaret E. Ferguson gave an account of investigations into the condition of germination of Basidiomycetous spores, and Prof. Conway Macmillan described his observations on Pterygophora.

THE new volume of the "Statesman's Year Book," edited by Dr. J. Scott Keltie, with the assistance of Mr. I. P. A. Renwick, has been published by Messrs. Macmillan and Co., Ltd. This annual is now in its thirty-ninth year of publication, and every year brings political and other changes which necessitate the revision of much of the information contained in its pages. So far as it is possible for a volume to reflect the condition of the States of the world, the "Statesman's Year Book" performs that function most creditably. Nothing of importance in political geography is overlooked; and the shifting scenes, figures and activities are faithfully recorded. The volume for 1902 contains much revised material relating to the accession of King Edward VII., the census of Great Britain and of India, the development of our educational system, and colonial changes. The maps and diagrams show the results of recent censuses at home and abroad, existing and projected railways in East Central Africa, the new Indian province, and the projected Central America canals. The contents now occupy 1332 pages, and the volume should not be permitted to exceed this number very largely, or it will lose its handy character. How the editor will prevent the ultimate expansion of matter beyond the present limits of space is a problem to which he will need to give careful consideration.

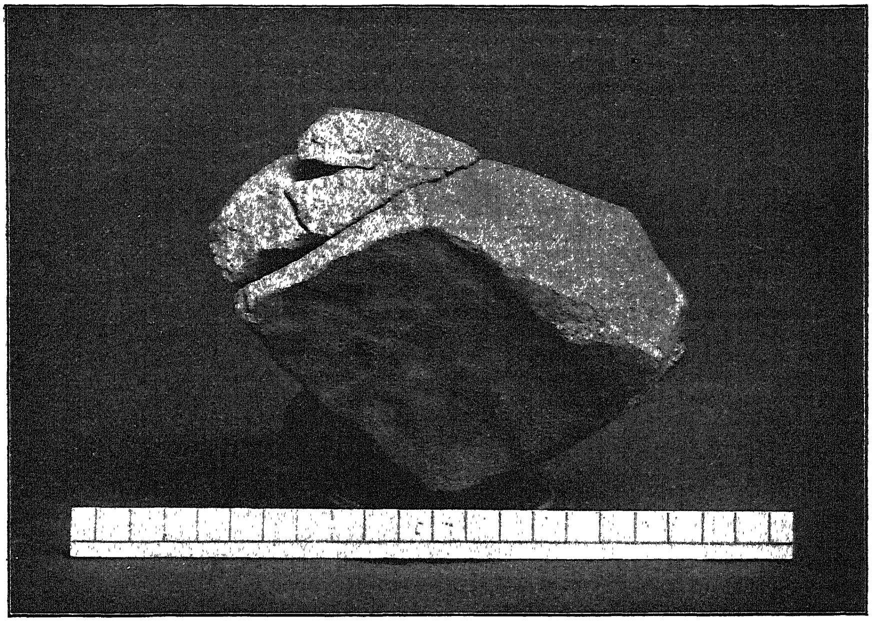
THREE new volumes of Ostwald's series of "Klassiker der exakten Wissenschaften" have been received from Mr. W. Englemann, of Leipzig. (London: Williams and Norgate.) The volume No. 119 (price 2*s.* 6*d.* net) contains two papers on hygrometry, by H. B. de Saussure (1783), edited by Dr. A. J. von Oettingen. The papers deal with the theory of evaporation and the application of the theory to some meteorological phenomena. No. 120 (price 3*s.* net) contains a German translation, with notes by Dr. M. Möbius, of two papers by Malpighi (1675 and 1679) on the anatomy of plants. Fifty figures illustrate the text, and the editorial notes will be of service to German students. Two papers on plant hybrids, by Gregor Mendel (1865 and 1869), edited by Dr. E. Tschermak, form No. 121 of the series. The price of this volume is 1*s.* net.

A NEW edition (the tenth) of Mr. W. T. Lynn's booklet on "Remarkable Comets" has been published by Messrs. Sampson Low, Marston and Co. The only comet expected to return this year is Swift's comet, having a period of 5½ years. This is due towards the end of the year.

THE additions to the Zoological Society's Gardens during the past week include two Black Apes (*Cynopithecus niger*) from the Celebes, presented by Miss A. T. M. Elliot; a Malayan Bear (*Ursus malayanus*) from Malacca, presented by the Marquis of Downshire; a Suricate (*Suricata tetradactyla*) from South Africa, presented by Mrs. Philips; a Golden-naped Amazon (*Chrysotis auripalliata*) from Central America, a Yellow-billed Amazon (*Chrysotis panamensis*) from Panama, seven Elegant Terrapins (*Chrysemys scripta elegans*) from North America, two Wrinkled Terrapins (*Chrysemys scripta rugosa*) from the West Indies, deposited; six Ruffs (*Machetes pugnax*), four Snow Buntings (*Plectrophenax nivalis*) European, eight Undulated Grass Parrakeets (*Melopsittacus undulatus*) from Australia, purchased: an Eland (*Orias canna*) born in the Gardens.

OUR ASTRONOMICAL COLUMN.

THE FELIX METEORITE.—In a recent number of the *Proceedings* of the United States National Museum, Mr. G. P. Merrill gives an account of the fall of a meteoric stone at 11.30 a.m. on May 15, 1900, near Felix, Alabama. A luminous meteor was seen and three loud reports as of explosion were heard. The main mass weighed about 7 lbs. and was found buried six inches deep in soft ground. In aspect of fractured surface the material is like that of the stones of Warrenton and Lancé, but the chondritic character is more pronounced than in the latter and the colour is darker than in the former, owing to the presence of graphitic carbon in appreciable quantity. The essential minerals are, olivine (73 per cent.), augite and enstatite (18 per cent.), with troilite (5 per cent.), nickel-iron (3 per cent.) and graphitic carbon (0.4 per cent.): the micro-structure is tuff-like.



The Felix Meteorite. The scale below the meteorite is divided into centimetres.

ON THE RELATION BETWEEN INTELLIGENCE AND THE SIZE AND SHAPE OF THE HEAD.

THERE is a popular belief that men of great ability have larger heads than the average population; this belief, however, is not based on trustworthy statistics handled in a satisfactory manner.

In a paper read before the Royal Society, January 23, Prof. Pearson gives the results of statistical investigations undertaken with a view to determine whether any head measurements, and if so, which, are correlated with intellectual capacity.

He points out that although the professional classes are more intellectual and have a larger mean head capacity than the hand-working classes, this does not lend any support to the current notion; for the former are better developed physically, and the difference is probably only due to difference of nurture. It is necessary to take a homogeneous class in order to investigate the matter.

The Cambridge Anthropometric Committee furnished a series of measurements made on Cambridge undergraduates, and information was obtained from the University Registry of the degree (honours or poll, class-place, subject, &c.) taken by each of the individuals whose measurements were given.

The undergraduates furnish a homogeneous class of the same general habits.

They were divided into two groups—honours and poll men—and fourfold tables were made for:—

(1) Cephalic index and degree; (2) length of head and degree; (3) breadth of head and degree.

The table for (1) will illustrate the method in which all the tables were made.

Cephalic Index.

		Under 80.	Over 80.	Total.
Ability	Honours ...	307·5	216·5	524
	Pass	276·5	210·5	487
	Total.........	584	427	1011

The tables were worked by the method given in Prof. Pearson's memoir "On the Correlation of Characters not Quantitatively Measurable" (*Phil. Trans.*, vol. cxcv. A., pp. 1–47).

The divisions taken for length were under 7″·65 and over 7″·65, and for breadth over 6″·05 and under 6″·05. The correlation between ability and dolichocephaly was found to be ·0305 ± ·0349; between ability and long heads ·0861 ± ·0332; between ability and broad heads ·0450 ± ·0322.

If the numbers here given were of sensible magnitude, they would lead to the conclusion that ability is directly correlated with increased length and with increased breadth of the head and also with dolichocephaly. But on a comparison of the numbers with their probable errors it is seen that the correlation has no significance in the cases of cephalic index and of breadth; in the case of length, the correlation is between two and three times the probable error, but it is in itself too small to be of any real importance.

The Cambridge results may consequently be taken to show that there is no marked correlation between ability, as judged by entry for an honours examination, and the size or the shape of the head.

The problem was next worked out from a series of measurements made in schools. The data here are less satisfactory, for the measurements were made in schools of all grades all over the country, and consequently give a mixture of classes and of ages.

The cephalic index remains practically constant during growth; children of all ages may therefore be put together in this measurement; the length and the breadth of the head change with age, and the measurements in these cases must be reduced to the same age.

This was done by forming tables of correlation between length of head and age, and between breadth of head and age.

1856 boys were taken of ages running from four to nineteen years; the mean length was found for each year of age and a curve obtained of the average length of head of boys from four to nineteen years of age.

This curve showed apparently a period of rest in growth during the twelfth year. (A similar but less-marked rest in the twelfth year is also shown by T. W. Porter's curves for growth of head of St. Louis boys.)

The twelfth year was consequently chosen as the standard age to which all the measurements were reduced. The growth of the average boy for every year of age was then found. These values were added to the lengths for boys under twelve and subtracted from the lengths for boys over twelve. This gives what would be the length of head at twelve under the assumption that each boy grows like the average boy; this is, of course, not actually the case, but for a broad classification will hardly lead to serious error.

The same method was applied to the measurements on the breadth of head.

The children were arranged by their schoolmasters into the following classes:—

Quick-Intelligent, Intelligent, Slow-Intelligent, Slow, Slow-Dull, Very Dull.

In forming the correlation tables for ability and head-measurements, Quick-Intelligent and Intelligent were placed in one class and all the rest into a second class, called respectively Intelligent and Slow.

The divisions for cephalic index were taken as under 78·5, over 78·5; for length of head (reduced to twelfth year) below 184·5 mm., above 184·5 mm.; and for breadth of head (reduced to twelfth year) below 145 mm., above 145 mm. The results found were:—

Correlation between ability and dolichocephaly = ·0052 ± ·0240
Correlation between ability and long heads = ·0437 ± ·0242
Correlation between ability and broad heads = ·0843 ± ·0240

The results are in complete agreement with the Cambridge results.

The Cambridge and the school results taken together give practically a (mean) correlation of ·065 between size of head and ability. This value was taken and the class of people considered who have an ability so great as only to occur in 2 per cent. of the population—a fairly high standard. This was worked out by the tables of the probability integral, and it was found that 44 per cent. of the population have heads as large or larger than the mean head of the exceptional 2 per cent. of the population. Conversely, 44 per cent. of the population are as able or abler than the 2 per cent. of the population with exceptionally big heads.

But as 50 per cent. of the population are abler or larger-headed than the mean of the population, the above result shows the smallness of the basis upon which the argument from ability to largeness of head, or *vice versâ*, depends.

The Cambridge statistics were then investigated in the following manner. The honours men were divided into the three classes taken in examination. Two tables were made; in the first table, first- and second-class men were put in one division and third-class men in another, and a fourfold table was made with cephalic index. The correlation between ability and dolichocephaly came out = ·0641 ± ·0487. In the second table, the first-class men were taken alone for one division, and the second- and third-class men formed the second division; the correlation was found to be = − ·0254 ± ·0490. The numbers in both cases are non-significant; there is no evidence to show that ability as tested by examination is related to shape of head.

Corresponding tables were made for length of head and for breadth of head. The results were:—

Length (first and second classes together) ...	correlation = ·0865 ± ·0471
Length (second and third classes together) ...	correlation = ·1263 ± ·0439
Breadth (first and second classes together) ...	correlation = ·0056 ± ·0475
Breadth (second and third classes together) ...	correlation = ·1689 ± ·0478

These results seem to show an increasing correlation between ability and size of head when the first-class men are separated from the rest, but it seems possible to attribute the divergence of the results to other causes. Length and breadth of head increase with age, and here, on the whole, the honours men are older than the poll men and the first-class men than the second, for a considerable number of resident dons were included in the measurements of the honours classes.

Of course the scale of intellectual ability must always be a vague one. A man is reputed to be "able" by his contemporaries, but future ages may rate him as of small importance. All we can do is to take a more or less popular appreciation. The examiner's test is not a perfectly satisfactory one, but it is idle to suppose that *on the average* it does not distinguish between the able and the dull. The same may be said of the teacher's estimate; it is far from absolutely correct, but it is reasonable *on the average* and better than the examiner's. Lastly, we have the youth's own opinion of his capacity, as judged by the reading for a poll or honours degree. Tried by all these three tests, there is in the general population very insignificant correlation between ability and either the size or shape of the head. Very brilliant men may have a slightly larger head than the average, but the increase is so small that no weight can be laid on it in our judgment of ability.

THE EXPLORATION OF THE ATMOSPHERE AT SEA BY MEANS OF KITES.

FOR some years past, kites have been persistently and successfully employed by Mr. A. L. Rotch at his observatory at Blue Hill, U.S.A., for obtaining a knowledge of the movements, temperature and humidity of the upper air, and heights of three miles have been reached; their use was also systematically begun about the same time on the continent of Europe, especially at M. Teisserenc de Bort's observatory at Trappes, near Paris, where altitudes exceeding those at Blue Hill have been attained. We have also frequently referred to similar experiments both with kites and balloons made at the request of the International Aëronautical Committee. Valuable results have been obtained and published, so far as the land is concerned, and experiments will, we believe, be undertaken in this country under the superintendence of the Royal Meteorological Society. But in order to raise the kites to any considerable height, a wind of certain velocity is necessary. Mr. Rotch's flights were made when the wind velocity on the ground was between twelve and thirty-five miles per hour, and he points out that certain types of weather, such as anti-cyclonic conditions, with very light winds, or stormy conditions, can rarely be studied by that means.

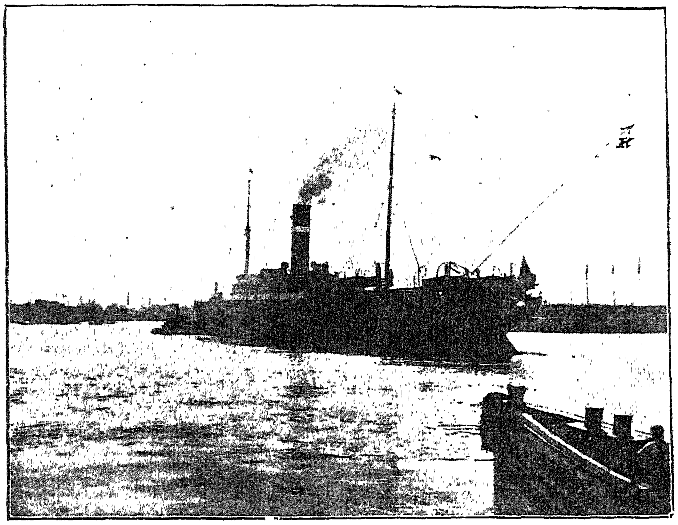


FIG. 1.—S.S. *Commonwealth* leaving Boston (kites were flown from K).

The prediction of weather for a day or so in advance has been brought to considerable perfection by the combined efforts of various meteorological services and the publication and study of synoptic weather charts; but further progress is necessary, and we believe that it is to the investigation of the upper air, especially if, as has been suggested, observations could be carried out in equatorial and trade-wind regions, where the changeable conditions of our latitudes do not exist, that further advance in weather knowledge may be confidently expected.

The plan proposed in a paper recently communicated to the Royal Meteorological Society by Mr. Rotch, and published in its *Quarterly Journal* for January last, with reference to the extension of kite observations to the sea, will doubtless lead to important results, and such observations will show whether the conditions prevailing over the ocean differ materially from those existing over the land. We give illustrations of Mr. Rotch's endeavour to obtain data with kites sent up from the s.s. *Commonwealth* while crossing the Atlantic, through the courtesy of Captain J. McAuley. Fig. 1 shows the vessel leaving Boston on August 28, 1901, and the position from which the kites were flown, while Fig. 2 shows the installation of the kite-reel on the after-deck of the vessel.

The kites can be used on ships to better advantage than on land. For example, even when the air is calm, by steaming through it at a speed of ten or twelve knots the kites can be raised to the height they would reach in the most favourable natural wind, and attain the altitude of the upper air-currents. During the passage of the *Commonwealth*, anticyclonic conditions mostly prevailed, and the wind blew only four to twelve miles an hour; but as the vessel steamed about fifteen knots, it was possible to use the kites on five days out of eight occupied in crossing the Atlantic. In one of the flights it was found that the air was 5°·6 warmer at a height of 130 metres than it was at the sea-level, and remained so during the afternoon (August 31). Another advantage gained by flying kites from a steamship is that wherever the observations in the upper air may be made there is always the observing station on the ship at sea-level, and not far distant, horizontally, with which to compare them.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

THE Technical Instruction Committee of the City of Liverpool is the recognised local authority through which the Board of Education deals with all the science and art classes in the city with only two exceptions. The Committee carries on its work through many agencies in an organised plan, and every year several important developments are recorded. From the Report for the year 1901 we learn that the committee again renewed the grant of 200*l*. in aid of the scientific work carried on by the Lancashire Sea Fisheries Joint Committee. A permanent sea fisheries laboratory in the zoological department of University College, under the direction of Prof. Herdman, is partly supported by this grant; and trained assistants are constantly at work in this laboratory, investigating fisheries' questions that may arise in connection with the local industries. One of the rooms of the zoological museum at University College is devoted to a permanent fisheries collection, illustrating the local fishing industries, but no part of the grant made by the Technical Instruction Committee is expended on this museum. In connection with courses of lectures to gardeners on plant diseases, given by Prof. Harvey Gibson, a course of special lectures, followed by practical work in the botanical laboratory, has been arranged in the new Hartley Botanical Laboratory at University College. This attempt to show practical working gardeners the scientific methods of

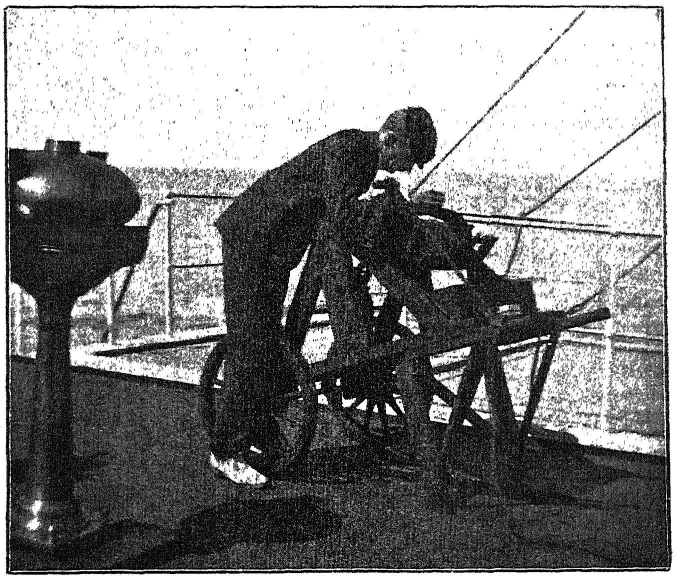

FIG. 2.—Kite-reel on after-deck of s.s. *Commonwealth*.

observation and investigation into such problems as those of plant disease is likely to be of the greatest value.

THE Report of the Technical Education Committee of the Derbyshire County Council states that the Technical School at Glossop, erected by Lord Howard of Glossop, has during the past year been furnished and equipped by the Glossop Town Council, aided by a grant of 600*l.* (in addition to the loan of chemical and physical apparatus) from the County Council. There are now nine schools of science in the administrative county, of which seven are co-educational schools for boys and girls. It is sometimes complained that the "school of science" curriculum is not sufficiently commercial, but early specialisation in purely commercial subjects, such as bookkeeping, commercial geography and business letter writing, should certainly not be encouraged. The Committee quotes in this connection Mr. Sydney Webb's remarks that "English business is not being driven to the wall because of a dearth of qualified clerks and trained office boys. . . . What we have to do is to train our business men, be they clerks or partners, not merely or even chiefly to discharge their office routine, but to let their intellects play round their business, to put into their work, not only brains, but brains of the highest or inventive kind. This is where they seem at present to fall behind the German and the American. Now we may take it for granted that we cannot get business men of wider minds by narrowing their education, nor produce that heightening of the imagination which makes discoveries by carefully shutting out all knowledge of the world that is not business. The most efficient business man, in this highest sense of the word efficient, will, we may be sure, not be an uncultivated man nor a man of narrow range."

SCIENTIFIC SERIALS.

Bulletin of the American Mathematical Society, February.—Prof. F. N. Cole is the chronicler of the proceedings at the eighth annual meeting, in New York City, of the Society on December 27, 28, 1901. Though now two days are devoted to the conference, owing to the large number of papers sent in (twenty-seven), this time is hardly adequate, and it is becoming a serious question whether it will not be necessary to adopt a practice of selection, permitting the presentation, even then in condensed form, of more important papers only. The meeting was largely attended, the number of members present amounting to fifty-nine. A social feature was the dinner on the Friday evening. The officers and members of council were elected. Sir Robert Ball was present, and amongst the abstracts of the papers communicated is that of his recent researches in the theory of screws. Miss Scott's paper on a recent method for treating the intersections of plane curves investigates the nature of the set of equations discussed in Dr. F. S. Macaulay's paper in the London Mathematical Society's *Proceedings*, vol. xxxi., giving different and simpler proofs of the theorems obtained by Dr. Macaulay.—Prof. Holgate gives an account of the proceedings at the January meeting of the Chicago section, held at Evanston, Illinois, January 2, 3, 1902. Here also the attendance was unusually large. Nineteen papers were presented, and abstracts of them are here given. "The Vector Analysis" of Dr. E. B. Wilson is reviewed by Prof. A. Ziwet. Prof. Gibbs's "Elements of Vector Analysis" (1881–4) attracted wide attention, though it was only a pamphlet (83 pp.) printed for the use of his students. This Mr. O. Heaviside adopted, with slight modifications, and expounded fully in his "Electromagnetic Theory" (1893). Dr. Wilson's work is founded upon Prof. Gibbs's course of lectures delivered in 1899–1900, and gives the first generally accessible authentic record of Prof. Gibbs's system. The additions to the theory of the (1881–4) pamphlet are not extensive, though Dr. Wilson's book runs into 436 pp. This bulkiness is due to the lavishly open print and partly to the author's effort to make the subject easily intelligible by supplying numerous illustrations and applications. A good index is a desideratum, and the printing details lack the advantage of external aids now so common in carefully printed mathematical text-books.—Mr. J. L. Coolidge gives an interesting notice of Dr. Max Simon's "Euclid und die sechs planimetrischen Bücher" and of Prof. M. J. M. Hill's "The Contents of the Fifth and Sixth Books of Euclid."—The notes and new publications give the usual interesting information.

Memoirs (*Trudy*) *of the Kazan Society of Naturalists*, vol. xxxiii., 5 and 6.—Researches into the soils and flora of the Penza and Gorodische districts, by J. Sprigin.—On the Erinaceæ of Russia, by K. Satunin (with one plate). The following five species, found in European Russia, Caucasia and Transcaspian territory, are described:—*Erinaceus europaeus*, *E. auritus*, *E. albulus*, *E. macracanthus* and *E. hypomelas*.

Vol. xxxiv.—This volume is dedicated by the Society to the professor of geology, Alexander Antonovitch Stuckenberg, whose portrait is given.—The Plagioclase-augite rocks between the Yenisei and the Lena, by A. Laversky. A large collection of 350 specimens of these rocks was made thirty years ago by Czekanowski and is now described, the author giving also a general geological review of the region. Cambrian and Silurian deposits constitute the frame of the plateaus. They are covered with coal-bearing, brown Jurassic deposits (perhaps also Miocene), and the latter are pierced and covered with basalts, breccias and volcanic tuffs, which in their turn are occasionally covered with post-Pliocene deposits. The sheets of basalt seem to have been ejected immediately after the deposition of the coal-bearing sandstones, and cover an immense space—larger than anywhere else on the globe—and are similar to the basalt sheets of Novaya Zemlya, Franz Josef Land, Greenland, Jan Mayen, Iceland and the north-western portion of Great Britain. A map and several plates, as also a summary in French, accompany this excellent and very elaborate work.—Materials for the fauna of the Devonian deposits of the Urals, by P. Kazansky, with one plate (summed up in German).—Materials for the knowledge of the soils and the vegetation of Western Siberia, by A. Gordyaghin, part i. Under this modest name the author gives, as an introductory chapter, an excellent description, geographical, geological and botanical, of the region in the basin of the Irtysh (from 49° to 61° N. lat.), where we see the gradual transition from the black-earth steppes to the forest region. Some very interesting discussions about desiccation and the periodical changes in the precipitation in Western Siberia are incorporated in this chapter.—On the Turbellariæ of the Solovetsk Islands, by I. P. Zabusoff. Descriptions of the thirty-nine species, some of which are new, which were found in this part of the White Sea, and anatomical descriptions of four especially interesting forms (long summary in German, and three large plates).—The fauna of the Carboniferous limestone on Shartymka River, on the eastern slope of the Urals, by M. Ianishevsky (seven plates and one map). No less than 328 different species, some of which are new, are described, and the conclusion is that these limestones (described already by Verneuil and Murchison) seem to belong to the Lower Carboniferous age.—First addition to the "Fauna of the Permian Deposits of Eastern European Russia," by A. Netchayeff, with three plates. Eighteen species, of which nine are new, are described in Russian and in German.

Bulletin de l'Académie des Sciences de St. Pétersbourg, 5e série, tome xi., 1–5.—Observations of minor planets, made at Pulkova with the 15-inch refractor in 1898 and 1899, by W. Séraphimoff. The positions of thirty-five minor planets are given.—Observations of terrestrial magnetism at Obdorsk and Samarovo (North Siberia), by H. Abels.—On the products of oxidation of the new alkaloid cotarnine, by G. Wulff.—On the determination of the form of the solar disc, by W. Ceraski.—Actinometric measurements at Ekaterinburg, by P. Müller.—Determination of the velocity and direction of motion of clouds, by V. Kouznetsov (according to Pomortseff's method), with a plate.—Researches into the coefficient of refraction of ethyl ether in the vicinity of the critical point, by Prince B. Galitzin and J. Wilip (in German). The chief results of this elaborate work are: the critical temperature is 193°·61 C.; critical pressure, 36·28 atm.; critical volume, 3·84 c.c. The formula of Lorentz represents very well the relations between the refraction-coefficient and the volume, and covers a wide range of temperatures (10° to 100°), both for the liquid and the gaseous states. The Lorentz constant is $C = 0·3025$. "It must also be admitted that in certain circumstances the liquid state may persist above the critical point—a phenomenon which is quite analogous to the retardation of evaporation."—Contributions for explaining various information from oriental sources about Eastern Europe, by F. Westberg. A learned and very interesting series of researches about the information found in these sources about different nations—the Rûs, the Madjars, the Vyes, and so on.—On the classification of the Chrysomonades, by L. Iwanoff (in German). Certain peculiarities of structure

of the genus Mallomonas permit the author to establish a classification of this difficult division.—A new archaic inscription of the Roman forum, by A. Enmann.

Bulletin du Jardin Botanique de St. Pétersbourg, tome ii. fasc. i.—On the causes of the absence of wood on the *yailas* (high mountain plateaus) of Crimea, by G. J. Tanfiljew. The cause is probably in the late thawing of snow—often in May only—and the consequent saturation of the soil with water.—Lichenological notes, by A. A. Elenkin. – Communications.

Memoirs of the Novorossian (Odessa) Society of Naturalists, vol. xxiii., 2.—Remarks on the Crimean stag, by A. Brauner (two plates). Unlike Ward, Nikolsky and Lydekker, the author considers this stag as *C. elaphus*, L., which is near, not to the typical individuals from the forests, rich in food, of middle Europe, but to the island type (also mountain and southern type), and especially to the Corsican representative of this species (summary in German).—On the nitrification of water, by E. Gredig.—Note on the Sarmatian deposits of Transcaucasia, by V. Lashkarev, on the basis of Prof. Ernest Favre's collection at Geneva.—Fauna of the caves of Crimea, by J. Lebedinski, with one plate. First attempt to explore these caves.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, November 28, 1901.—"Micro-crystalline Structure of Platinum." By Thomas Andrews, F.R.S.

The crystalline structure of platinum does not appear to have been studied, although it forms an interesting subject for investigation. A small ingot of pure platinum was obtained for the experiments. A section was cut therefrom and machined to 5/16th inch square and 1/10th inch in thickness. The section

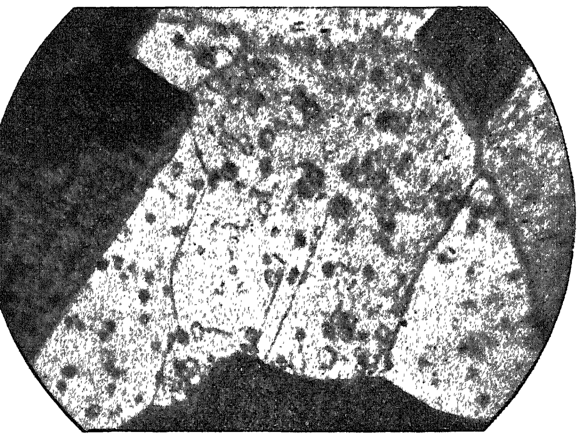

FIG. 1.—Micro-crystalline structure of platinum as seen in section at 360 diameters.

was then carefully polished and etched in aqua regia. The etching was very difficult and required the greatest care in manipulation to satisfactorily develop the crystalline structure. The result of the etching was the development of a beautiful crystalline structure which manifested, not only the large or primary crystal grains, but also the secondary or very minute crystalline development which is illustrated on a plate accompanying the paper, as seen in section at magnifications respectively of 50, 120, 360 and 360 diams. The last two of these figures are here reproduced. The larger or primary crystal grains were observed to consist of irregular polygons of varying size, the etched indications of the facet junctions being often clearly and sharply defined. The minute or secondary crystals (whose intercrystalline junctions were also clearly seen) were in the mass observed to be in varied positions of orientation, but the orientation was generally identical, or on the same plane, within the area of each larger crystal grain. The general orientation of the smaller crystals varied, however, in each separate larger crystal, and the consequent varied reflection of the light has given the face of the microsections, as a whole, the appearance of lighter or darker areas in the photomicrographs. In some portions of the mass there were observed minute triangular crystals; these appear, however, to be only developments resulting from the cutting of certain crystals in section. The general microcrystalline structure of platinum was observed to be allotriomorphic in character

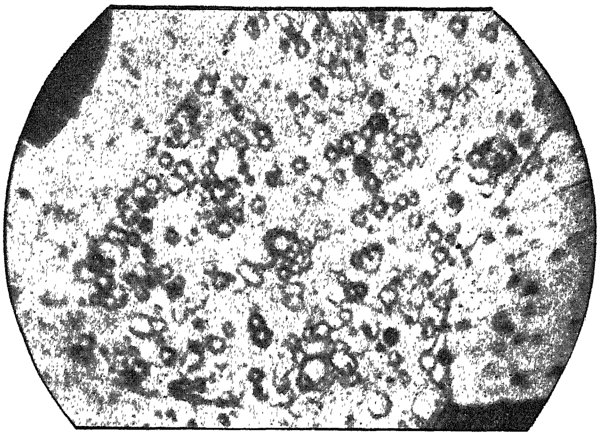

FIG. 2.—Micro-crystalline structure of platinum as seen in section at 360 diameters.

and derived from a system of interfering cubes and octahedra, the cubic and hexagonal form being frequently noticeable. The size of the large crystal grains varied from about 0·002 inch to 0·04 inch in size, and the smaller crystals ranged from about 0·0002 inch to about 0·007 inch. There were indications that the smaller or secondary crystals were each built up of even more minute crystalline ramifications. The crystalline structure of platinum appears to generally resemble that of gold and silver. The descriptive words "primary" and "secondary" crystals are only used in relation to size, and they are not intended to convey the idea of distinctive times of formation during solidification.

February 13.—"Preliminary Note on a Method of Calculating Solubilities and the Equilibrium Constants of Chemical Reactions, and on a Formula for the Latent Heats of Vaporisation." By Alexander Findlay, M.A., B.Sc., Ph.D. Communicated by Prof. Ramsay, F.R.S.

If R and R′ represent the ratios of the absolute temperatures at which two substances have the same solubility, the author shows that $R = R' + c(t' - t)$, where c is a constant having a small positive or negative value and t' and t are the temperatures at which one of the substances has the two values of the solubility in question. The formula is precisely similar to that which Ramsay and Young showed to hold in the case of vapour pressures (*Phil. Mag.*, 1886, xxi. 33). Given the solubility curve of one substance it is therefore possible to calculate the solubility of a second substance provided the solubility of the latter at two temperatures is known. The author shows that this method can be applied to the calculation of "equilibrium constants" of chemical reactions.

It is further shown that if L_1 is the known latent heat of vaporisation at the absolute temperature T_1 of one substance, and L_2 the latent heat of the second substance at the temperature T_2 at which the vapour pressure of the second substance is equal to that of the first at the temperature T_1, then $L_1/L_2 = T_1^{x_1}/T_2^{x_2}$. A less exact, but simpler formula is $L_1 = L_2 T_2^x$. These formulæ appear not to be applicable when the pressure exceeds 10,000–20,000 mm.

February 20.—"On a Pair of Ciliated Grooves in the Brain of the Ammocœte, apparently serving to promote the Circulation of the Fluid in the Brain-cavity." By Arthur Dendy, D.Sc., F.L.S., Professor of Biology in the Canterbury College, University of New Zealand. Communicated by Prof. G. B. Howes, F.R.S.

The author demonstrates the existence in the brain of the Ammocœte of a pair of remarkable ciliated grooves. The structures in question were discovered by the author in the

Ammocœte of *Geotria australis*, the New Zealand lamprey, and subsequently he found similar organs in sections of an Ammocœte of *Petromyzon* in the zoological laboratory of Owens College. The grooves in question run along the roof of the brain-cavity from about the hinder margin of the posterior commissure to the *recessus subpinealis*. They are lined by a sharply defined epithelium of very long columnar cells, and their concave surfaces are covered with short cilia. The function of these organs is apparently to promote the circulation of the fluid in the brain-cavity, and this view is supported by the arrangement of the choroid plexuses. In the New Zealand Ammocœte the choroid plexus of the mid-brain dips down into the *iter* in the shape of a highly vascular longitudinal septum dividing the upper part of the brain-cavity in this region into right and left halves, and it is significant that the ciliated grooves are so arranged as probably to direct a stream of brain-fluid along each side of the septum. It has been already suggested that the choroid plexuses of the vertebrate brain are concerned with the gaseous interchanges which take place in the cavities of the ventricles. In the young Ammocœte the first choroid plexus, which may be supposed to be especially concerned in the respiration of the fore-brain, is not yet developed; the second and third choroid plexuses, belonging respectively to the mid- and hind-brain, are, on the other hand, already extensive. We need not, therefore, be surprised to find that the fore-brain at this stage is dependent to a large extent for its means of respiration, and perhaps also for its nutrition, upon the choroid plexus of the mid-brain, and that a special apparatus in the form of ciliated grooves is developed for securing a forward flow of the necessary fluid in the brain-cavity.

March 20.—"On the Development of the Layers of the Retina in the Chick after the Formation of the Optic Cup." By John Cameron, M.B., Ch.B. (Edin.) Communicated by Prof. Macintosh, F.R.S.

The inner wall of the retinal cup in a fourth-day chick has exactly the same structure as the wall of the embryonic cerebral vesicle or spinal cord at the same date. All the structures which His has described in the wall of the embryonic spinal cord can be also recognised here, and may, therefore, receive similar names—thus, there is a network (the myelospongium) which is formed by spongioblasts, and between the fibres of the myelospongium are found germinal cells which divide to form neuroblasts. From the latter are formed the cells of the outer and inner nuclear layers and the ganglion cells of the retina. On the eighth day the internal molecular layer appears, and on the ninth day the external molecular layer. The first appearance of these layers is due to a rearrangement of the myelospongium, and they map out the three cellular layers. Three kinds of cells are found in the internal nuclear layer at the twelfth day—amacrine, bipolar and basal cells. The cells of the external nuclear layer become rod and cone cells, and from them rods and cones begin to develop on the twelfth day of incubation. The hexagonal pigment cells develop from the outer wall of the retinal cup, and their processes also appear on the twelfth day.

Linnean Society, March 6.—Mr. Herbert Druce in the chair, succeeded by Mr. A. D. Michael.—Mr. J. E. Harting exhibited and made remarks upon some unpublished coloured drawings by Messrs. J. G. Millais and A. Thorburn of British freshwater Anatidæ illustrating intermediate phases of plumage, through and irrespective of moulting, not hitherto figured.—A paper by Prof. A. Gruvel, of Bordeaux, was read, dealing with some cirrhipedes preserved in the British Museum of Natural History. The chief feature of the paper was the introduction of several new families into the group Lepadidæ as accepted by Darwin, and modified by Gerstäcker by the separation from it of the Alcippidæ for a single species.—The zoological secretary gave an abstract of a memoir by Prof. Elliott Smith, of Cairo, "On the morphology of the brain in the mammalia, with especial reference to that of the lemurs, recent and extinct." The author has examined either the brain or cast of the brain-cavity of every lemuroid genus living and extinct, and his work is the result of an investigation of the collections of the Royal College of Surgeons Museum, the British Museum, the Zoological Society, aided by gifts of material by Captain Stanley Flower, Mr. Hose, and other persons named. A critical *résumé* of the literature of the subject is followed by a detailed consideration of the sulci, the calcarine and sylvian fissures receiving special attention. The author shows that the simplest lemuroid type of brain is that of the Galaginæ, the most specialised that of the Indrisinæ and Lorisinæ. He shows that in Cheiromys the individual variation of the sulci is so great that the suprasylvian and lateral fissures alone remain unchanged, and he finds proof in this genus of ontogenetic retrogression, which substantiates the conclusions of Forsyth-Major originally deduced from the study of the living Galaginæ, the Tertiary genus Microchœrus, and more recently from that of the Madagascar genera Globilemur and Megaladapis. For Tarsius he shows, while the brain, in respect to its occipital overlap and the presence of a posterior cornu, as also to the assumption of the microsmatic condition, is the most pithecoid of that of all lemurs; conversely, in the characters of its corpus callosum, hippocampus and cerebellum, it is shown to conform to the lowest Eutherian type. Regarding Tarsius as a lemur, the author concludes that the lemuroid brain is intelligible only on the supposition that it has advanced along the main primate stem and later undergone retrogression. A caudo-occipital curtailment of the hemisphere is regarded as the dominant change which the lemuroid brain has undergone, with accompanying structural simplification; and evidence is adduced to prove that while the lemuroids were ancestrally macrosmatic, the macrosmatic condition at present found to exist in them has been secondarily acquired from a pithecoid microsmatic state, of the order of that retained in the tarsier. Beyond this, the memoir deals exhaustively with the comparative morphology of the pallium of the chief mammalian orders, with especial reference to confusion of ideas concerning fissures to which the term "sylvian" has been applied.

March 20.—Prof. S. H. Vines, F.R.S., president, in the chair.—Prof. J. C. Bose read a paper on electric response in ordinary plants under mechanical stimulus. He first explained his apparatus and methods, and then performed, with the aid of his assistant, a series of experiments showing electric response for certain portions of the plant organism, which proved that as concerning fatigue, behaviour at high and low temperatures, the effects produced by poisons and anæsthetics, the responses are identical with those hitherto held to be characteristic of muscle and nerve and of the sensitive plants. He drew the final conclusion that the underlying phenomena of life are the same in both animals and plants, and that the electrical responses which he had demonstrated are but the common physiological expression of these.—Dr. O. Stapf read a paper on the fruit of *Melocanna bambusoides*, Trin., an endospermless viviparous genus of Gramineæ. Fruits of this very singular grass collected last year were forwarded through Mr. Wild, Conservator of Forests, Bengal. They are of the shape and size of small apples or inverted pears, usually terminating with a short or long beak, the longest measuring as much as 5 inches in length. They consist of a hard, thick, fleshy pericarp, which contains a great deal of starch stored in a parenchymatic tissue, of a testa developed as nutrient layer and present in the mature fruit in an "obliterated" condition, and an embryo possessing an enormous ellipsoid scutellum which fills up the large central cavity of the pericarp, or is partly empty. The epidermis of the scutellum is developed as haustorial epithelium of the kind characteristic of grass-seeds, so far as it is in contact with the pericarp or, rather, the nutrient layer. It is traversed by numerous vascular strands which start from a plate of tangled strands in the axis of the embryo, and send out innumerable branchlets near the surface of the scutellum. The fundamental tissue in which the strands are embedded is delicately walled parenchyma, full of starch. There is no endosperm. Germination starts while the fruits are still on the tree, and the young shoots may attain a length of as much as 6 inches, whilst a bundle of roots is formed simultaneously. During germination, the scutellum acts on the pericarp as it acts in typical grasses on the endosperm, depleting not only the store of starch and other nutrient matter deposited in the cells of the parenchyma, but finally inducing also the partial solution of the cell-walls. This structure of the fruit of Melocanna is almost unique in grasses, and was not known before. It is probably repeated, although with some modifications, in the genera Melocalamus and Ochlandra, which the author intends to make the subject of another paper.—Messrs. A. O. Walker and Andrew Scott read a paper on Crustacea Malacostraca from the island of Abd-el-Kuri, in the Red Sea, collected by Messrs. H. O. Forbes and W. Ogilvie Grant during their expedition to Socotra in 1899. The specimens described were picked out of the residue from a collection of Algæ procured in April of that year, in rock pools

and tidal inlets on the above-named island. Of 13 species thus obtained, seven were described as new to science and three were regarded as belonging probably to new genera. One of these genera (Kuria), it appeared, could not be referred to any of the recognised families of Amphipoda.

Zoological Society, March 18.—Dr W. T. Blanford, F.R.S., vice-president, in the chair.—Dr. H. Gadow, F.R.S., read a paper on the evolution of horns and antlers. He stated that three main types could be distinguished in the evolution of the ornamental weapons on the heads of ruminants, and that all these types were referable to an ancient condition in which the beginning weapon, be it one of offence or defence, appeared as a mere exostosis with a thickened skin-pad. This stage resembled that of Dinoceras of the Eocene. Secondly, there was found exostosis of the frontal bone producing a pedicle, surmounted by a cartilaginous mass of apical growth, which by subsequent basal ossification became an antler. Skin originally unaltered and hairy; this, and the chondrostoma or cartilaginous later osseous growth, was shed periodically and constituted the cervine type. A side issue of type ii. was that of pro-giraffe-like animals. Cartilaginous growth preponderant, with multiple and broadened bases. Ossification delayed, but still proceeding from the base, *e.g.* the Samotherium of the topmost Miocene. A further development of this type (ii. *a*) was shown by the giraffe, in which the outgrowth proliferated freely and now formed free growths, ossifying independently, of the cranial bones, but ultimately fusing with them. Type iii. was a continuation of the main line from ii., represented by the prong-buck; predominant epidermal growth produced a horn-shoe, which was periodically shed, but had abolished the shedding of the bony core which represented the antler. Type iv., the highest stage, was represented by the hollow-horned ruminants, in which the horn-shoe was now a permanent feature; but it was important to note that these animals still shed the first, or earliest, generation of the horny sheath. Horns and antlers were developed alike with a cartilaginous matrix, with subsequent ossification. These four types were an illustration of onward phyletic evolution, and these stages were still faithfully repeated in the development of the recent species; this was a clear instance where ontogeny was a shortened recapitulation of phylogeny.—Mr. R. Trimen, F.R.S., communicated a paper by Lieut.-Colonel J. M. Fawcett, entitled "Notes on the Transformations of some South-African Lepidoptera." This memoir was in continuation of one by the same author, already published in the Society's *Transactions*. It illustrated the earlier stages of thirty-two species, of which six belonged to the Rhopalocera and twenty-six to the Heterocera.—Mr. R. I. Pocock gave an account of a new stridulating organ discovered in the scorpions belonging to the African genus Parabuthus. This organ consisted of a granular sharpened or finely ridged area upon the dorsal side of the seventh abdominal somite and of the first and second segments of the tail. The sound was produced by scraping the point of the sting over these granular areas.—A communication from Dr. R. Broom, on the organ of Jacobson in the elephant-shrew, was read, in which the author showed that the organ of Jacobson, which in Erinaceus was of the Eutherian type, was in Macroscelides marsupial in all its details, and was most nearly comparable to that of Perameles. Pointing out that in the allied genera Petrodromus and Rhynchocyon marsupial characters had been discovered by Parker in the skull, the author concluded that Macroscelides was "a very near relation of the marsupials, and had probably little affinity with the more typical insectivores." Dr. Broom noted that Macroscelides had a discoidal deciduous placenta, and that its young were born in a well-developed condition.—A communication from Mr. Frederick Chapman contained an annotated list of the collections of Foraminifera and Ostracoda made by Dr. C. W. Andrews on Cocos Keeling Atoll in 1898.—Mr. G. A. Boulenger, F.R.S., described three new species of fishes from the French Congo under the names *Allabenchelys longicauda* (gen. et sp. nov.), *Labeo lukulae* (sp. nov.) and *Chilochromis duponti* (gen. et sp. nov.).

Entomological Society, March 19.—Dr. F. Du Cane Godman, F.R.S., vice-president, in the chair.—Mr. W. J. Kaye exhibited a number of insects from British Guiana, many of them taken by himself, illustrative of Müllerian mimicry. Dr. DuCane Godman remarked that in these regions many different forms of the same butterfly would often occur within a radius of fifty miles, showing a wide range of variation.—Prof. E. B. Poulton, F.R.S., exhibited cocoons of *Malacosoma neustria* collected by Mr. Hamm in 1900, spun upon black-currant and apple-trees in his garden at Oxford. All of them had been attacked by birds through the leaf, this being the thinnest part of the cocoon, and the pupa thus more easily abstracted. With regard to the resting habit of *Hybernia leucophearia*, he said that Mr. Hamm had observed that this moth usually rested in a horizontal position. Dr. Longstaffe said that all the specimens he had observed on green stems affected a similar position, and that he had only found one on a birch-tree. Mr. M. Jacoby said that he never found the species on oak at all, but on palings, also in the same position, which facts Prof. Poulton said tended to show that the protective instinct of the species was retained in such localities.—Mr. G. T. Porritt exhibited two bred black *Larentia multistrigaria* from Huddersfield, and said that the dark form was rapidly increasing in Yorkshire. Of those already emerged and reared from the same brood, three were normal and two dark.—Dr. Frederick A. Dixey read a paper, illustrated by lantern slides, entitled, "Notes on some cases of Seasonal Dimorphism in Butterflies, with an account of Experiments made by Mr. Guy A. K. Marshall." He said that he had long since formed the opinion that *Catopsilia crocale*, Cram., was specifically identical with *C. pomona*, Fabr., and had suspected that the differences between them might prove to be seasonal in character. The belief in their specific identity was held by Piepers and by de Nicéville, neither of whom, however, thought that the dimorphism thus shown had any relation to the seasons. Colonel Yerbury said that a temporary rainfall in a dry season in dry places had a marvellous effect in producing intermediate and wet-season forms. Mr. F. Merrifield pointed out the difference between experiments upon tropical and European species. In the tropics there are not any very great distinctions of seasons and temperature, whereas in temperate climates the seasons are clearly marked off from one another. Prof. E. B. Poulton expressed his opinion that by breeding species through, Mr. Marshall had proved that one form gives rise directly to the other, the pairing of the two forms being a biological test of very considerable value. Colonel Swinhoe, Dr. Jordan and Dr. F. DuCane Godman also joined in the discussion.—Prof. Poulton, F.R.S., read a paper on mimicry illustrated by the Sanger-Shepherd three-colour process, supplementary to his paper read at the meeting of the Society on March 5.

Mineralogical Society, March 25.—Dr. Hugo Müller, F.R.S., president, in the chair.—Mr. G. T. Prior contributed a paper on the petrology of British East Africa, the result of examinations of the collection of rock specimens made by Prof. J. W. Gregory during his expedition to Mt. Kenya and Lake Baring in 1892–3, and of collections from the Uganda Protectorate made recently by Sir Harry Johnston. Descriptions were given of the three main groups of rocks, viz., the basement Archœan gneisses and schists, the Palæozoic shales and sandstones and the Tertiary volcanic rocks. The gneisses and schists are associated with dykes both of acid pegmatites and of basic diabasis and epidiorites, and also with granulitic rocks analogous to the Charnockite series of India and Ceylon. Of the Palæozoic Karagwe series a collection of ferruginous shales and siliceous schists from Unyoro was described. These rocks present striking similarities with those of Hatch's Hospital Hill series of the Transvaal and with rocks from the Ingwenyaberg, Swaziland, and a correlation between the Karagwe series and the Cape System of the Transvaal was suggested. The volcanic rocks consist mainly of soda-rich phonolitic rocks which have resulted doubtless from a nepheline-syenite magma. The lavas from the volcanoes of the Great Rift Valley and of Mt. Kenya and the region between are characterised, like those of the Canary Islands and the Azores, by the prevalence of anorthoclase, by the large amount of soda-amphiboles (cossyrite, catophorite, arfvedsonite) as well as of soda-pyroxenes and by the absence of sphene and noseau. They form a remarkable example of a rock-series showing a gradation in composition from basic phonolites, containing nepheline both in large phenocrysts and in the groundmass, through phonolitic trachytes containing no recognisable nepheline, to phonolitic quartz trachytes, and finally to acid riebeckite-rhyolites containing much quartz. The later eruptive rocks from Mt. Elgon and the western side of the Great Rift Valley present some points of distinction with the earlier erupted rocks. They are generally of a more basic character like those of Kilimanjaro as compared with those of Mt. Kenya. Another point of distinction is the presence in them of titanic acid in large amount, in the form of

perofskite in the more basic nephelinites, and as sphene in the phonolites which are of the more ordinary type without soda-amphiboles. Most of the specimens from Mt. Elgon and the neighbourhood consist of nephelinites, but in some of them the nepheline, both as phenocrysts and in the groundmass, is partially or wholly replaced by melilite. Examples of melanite-nepheline rocks allied to borolanite, and of monchiquite dyke-rocks from Mt. Elgon, were also described. A specimen of nephelinite from the neighbourhood of Ruwenzori containing much perofskite suggested the contemporaneity of the eruptive rocks of Mt. Elgon and of the volcanic region at the foot of Mt. Ruwenzori.

Royal Meteorological Society, March 19.—Mr. W. H. Dines, president, in the chair.—Mr. W. N. Shaw, F.R.S., read a paper on la lune mange les nuages, which was really a note on the thermal relations of floating clouds. He also exhibited an arrangement of apparatus whereby the conditions applicable in the case of a floating cloud can be experimentally realised.—Mr. F. J. Brodie read a paper on the prevalence of gales on the coasts of the British Islands during the thirty years 1871–1900. The total number of gales of all kinds dealt with during this period was 1455, the yearly average being 48·5, of which 10·6 were severe. The worst year was 1883, while the quietest was 1889. The stormiest month was January, 1890. At all seasons of the year excepting the summer, the prevalence of gales from south-west is greater than from any other quarter. The minimum of such gales is reached in the spring, when rather less than 20 per cent. are from south-west, more than half the storms being, however, from points between south-west and north-west. The prevalence of gales from polar directions is then at its maximum, more than 21 per cent. blowing from points between north and east. In the spring of 1883, out of a total of eleven gales no fewer than seven were from these quarters, the proportion being about three times the average. The highest velocities recorded were those at Fleetwood during the westerly gales on December 22, 1894, and on January 12, 1899. On the former occasion, for nine hours, from 7 a.m. to 3 p.m., the mean velocity was sixty-four miles per hour, and at 9 a.m. it reached a maximum of seventy-eight miles. It appears that on the average 43 per cent. of the storm systems which visit our coasts advance from some point of the compass lying between south and south-west, and travel towards some point lying between north and north-east. 39 per cent. have an easterly motion, while less than 1 per cent. move westwards. A mean of 264 cases shows that the deep cyclonic systems which visit our islands travel on an average at the rate of 24·1 miles per hour; in some cases, however, the rate was not more than eight or ten miles, while in others it amounted to forty, fifty and even sixty miles per hour. The author concluded his paper by exhibiting a series of weather maps showing the progress of some of the most notable gales during the period covered by the discussion.

CAMBRIDGE.

Philosophical Society, March 3.—Prof. Macalister, president, in the chair.—On a method of increasing the sensitiveness of Michelson's interferometer, by Mr. H. C. Pocklington. It is shown that the sensitiveness of Michelson's interferometer can be greatly increased if we can cause the interfering beams to be circularly polarised in opposite senses. This can be done approximately in the ordinary form of the instrument (with, however, an unsilvered inclined mirror) by placing an eighth-wave plate of mica in front of each of the perpendicular mirrors so that a principal axis of each plate is parallel to the line of intersection of the mirrors, and suitably choosing the plane of polarisation of the incident light. A theoretically better method, in which the inclined mirror and the compensating plate are placed rather less than a quarter-wave apart, is discussed, but it is concluded that only experiment can decide which will be the better method in practice.—The influence of currents in metals on reflected and transmitted light, by Mr. P. V. Bevan.—(*a*) On the conductivity of the vapours of the alkali metals; (*b*) on induced radio-activity, by Prof. J. J. Thomson. The investigation was undertaken with the intention of seeing whether the "induced radio-activity" shown by a metal rod after long-continued negative electrification in the open air would occur if the rod were placed in a closed vessel instead of outside in the open air. The closed vessel was a zinc gasometer 102 cm. high and 75 cm. in diameter; the vessel was insulated and used as one of the electrodes, the other electrode was a metal tube placed at the axis of the cylindrical gasometer. A potential difference of 800 volts between the cylinder and this rod was produced and the current between these electrodes was measured. This current was "saturated" and was therefore a measure of the total ionisation in the gas in the vessel; if the rod became radio-active, the ionisation and therefore the current would increase. The current was measured in the morning, and the rod in the vessel kept connected with the negative terminal of a Wimshurst machine for six or seven hours, when it was disconnected from the machine and the current again measured; if the gas in the vessel were not exposed to Röntgen rays whilst the rod was negatively electrified, the author was not able to detect any increase in the current through the gas as the result of the long negative electrification: if, however, the gas were exposed to Röntgen rays during the negative electrification of the rod, then a well-marked increase in the current took place—the increase being some 16 or 17 per cent.; this increase was due to some alteration in the rod and not to a change in the gas in the vessel, for if a rod similar to the one which had been electrified, but which had not itself been electrified, were substituted, the current sank to its former value. No increase took place in the current if the rod were positively electrified. A number of experiments were made on the currents through the vessel when the vessel was not exposed to rays and when the rod was not electrified. Rods of different sizes and different metals were tried—these all gave approximately the same current; if the rod were carefully wrapped round with dry filter paper, the current showed a decided increase, while if the filter paper were damp, the current was many times its value for the bare rod; the current in this case is greatest when the negative ions move up to the paper-covered rod—a large effect is also produced when the paper is wetted with brine or alcohol, but a solution of H_2O_2 produces by far the largest effect yet found.—On the Hall effect in gases at low pressures (second paper), by Mr. H. A. Wilson. The experiments described in this paper are a continuation of those described in the paper entitled "On the Hall Effect in Gases at Low Pressures" (*Proc.* Camb. Phil. Soc., vol. xi. pt. iv.), read to this Society last October. Measurements have been made of the Hall effect and electric intensity in the uniform positive columns in oxygen and hydrogen, and also of the variation of the Hall effect along the discharge in air at various pressures. The Hall effect in hydrogen is found to be capable of being represented by the equation

$$z = 2{\cdot}65 \times 10^{-2}\frac{H}{p},$$

where z is the transverse electric intensity or Hall effect, H the magnetic field and p the pressure in millimetres of mercury. The corresponding equation for oxygen is found to be

$$z = 3{\cdot}8 \times 10^{-3}\frac{H}{p}.$$

The electric intensities in hydrogen and oxygen are found to be given by the equations

$$X = 28\sqrt{p}$$

and $$X = 26{\cdot}9\sqrt{p} \text{ respectively.}$$

The results on the variation of the Hall effect along the discharge are shown by curves which resemble the curves showing the variation of the electric intensity along the discharge. The paper concludes with some theoretical discussion of the results.—On the extraction of the gases from one cubic centimetre of blood, by Mr. J. Barcroft.—On the coefficient of mutual induction between a circle and a circuit with two parallel sides of infinite length, by Mr. G. F. C. Searle.—Notes on Semper's larva, by Mr. K. Ramunni Menon.

EDINBURGH.

Royal Society, February 17.—Prof. Geikie in the chair.—Major W. B. Bannerman, superintendent of the Plague Research Laboratory, Parel, India, gave an account of the work carried on in the laboratory of which Mr. Haffkine is director in chief. A staff of fifty-three, of whom five are European, now occupies a huge building which has been in succession a Roman Catholic seminary, a Governor's residence, and a plague hospital. A detailed account was given of the preparation of Haffkine's prophylactic, which the Indian Government had adopted as a vaccine for the plague. Some interesting statistics were given showing that under precisely similar con-

ditions persons who had been inoculated were distinctly less liable to attack than those who had not been inoculated, that of the inoculated patients who were attacked by the plague a much smaller percentage of cases proved fatal, that the prophylactic was not harmful during the incubation stage of the disease, and that protection began to be effective twenty-four hours after injection, but was not complete until the tenth day. Profs. Fraser, Greenfield and Hunter Stewart took part in the after discussion, Prof. Fraser commenting especially on the fact that the vaccine, valuable though it had been proved to be, had not been shown to be able by itself to control a real epidemic of plague. He believed that more effective control would result from the policy of isolating patients and of enforcing better sanitation. Moreover, Haffkine's vaccine always produced a reaction which, he could not help thinking, might actually convert a case which would otherwise have terminated in recovery into a case which terminated in death. In reply Major Bannerman said he would never decry sanitary measures, but it was at present impossible to get the natives of India to appreciate the blessings of sanitation and the necessity of ventilation. The Government should be induced to introduce the teaching of hygiene into the schools, and it was an extraordinary fact that there was not a medical representative on the Viceroy's Council.—Dr. Hugh Marshall communicated a paper by Mr. J. K. H. Inglis and himself on the action of silver salts on solution of ammonium persulphate. The paper gave the results of measurements of the reaction velocity and of the influence exerted by other salts present in the solution. From these it would appear that the first part of the reaction, giving rise to the formation of peroxide of silver or similar compound, is much slower than the second part, which results in the formation of nitric acid.

March 3.—Sir William Turner in the chair.—Dr. Masterman read a paper on the early development of *Cribrella oculata*, Forbes, of which the leading points may be thus summarised. The segmentation is very variable, but always culminates in a solid morula, which is converted into a blastula by a remarkable process termed multiple egression. A normal gastrula is then produced and the blastopore closes. A process of cell-prolification then causes the formation of mesenchyme and hypenchyme (the latter filling the archenteron). In the bilateral larva the anterior cœlom gives rise to the pre-oral cœlom and to paired lateral cœloms as well as a small central cœlom; the posterior cœlom gives rise to left and right halves which fuse later. The left lateral cœlom becomes the hydrocœle; the right lateral the epigastric cœlom; the central cœlom forms the pericardium or dorsal sac; and the posterior cœlom forms the hypogastric cœlom. The transition from bilateral to radial stages throws light upon the peculiar torsion found in asterids and upon the homology of the mesoderm in echinoderms. A close comparison was drawn between the Cribella larva and Balanoglossus.—Messrs. A. E. Shipley and Edwin Wilson, in a paper on a possible stridulating organ in the mosquito, drew attention to a curious apparatus at the base of the wings of *Anopheles maculipennis*, an apparatus which had escaped the notice of both the systematist and morphologist. The structure is very complex, but consists essentially of a slightly movable bar provided with a series of well-marked teeth which in certain circumstances rasp across a series of ridges. It seems probable that as the wings are raised and depressed the movement of these two surfaces over one another may account for some of the characteristic buzzing of the mosquito.—Dr. Noel Paton gave an account of some observations on the amount of dissolved oxygen in water required by young Salmonidæ.—A paper was also read by Dr. James Scott on the influence of subcutaneous injections of large quantities of dextrose on the metabolism in the dog. It was found that dextrose injected in amounts varying from 5 to 7 grms. per kilo. was as far as possible acted upon by the general tissues of the body and not dealt with by the liver or at once secreted by the kidneys, and the result was a marked increase in proteid metabolism.

DUBLIN.

Royal Dublin Society, March 19.—Prof. Grenville A. J. Cole in the chair.—On the progressive dynamo-metamorphism of a porphyritic andesite from co. Wicklow, by Henry J. Seymour. The author described the gradual alteration of a coarsely porphyritic andesite into a finely banded crystalline schist, as the result of earth movements connected with the intrusion of the Leinster granite. The light-coloured bands in the schist consisted of the very much elongated felspar phenocrysts, which are drawn out partly by granulation and partly by recrystallisation into flat lenticles seven or eight times the length of the original crystal from which they were derived. The dark bands are composed of the altered matrix containing abundant secondary biotite.—Prof. E. J. McWeeney, on a method of air-examination by bacteriological procedure. The problem to be solved was whether the air on a certain part of the premises of a Dublin manufacturer was liable to contamination by micro-organisms carried by air currents from a refuse-heap on the premises of a neighbour, the intervening distance being 800 feet. The method consisted in liberating on the refuse-heap a readily recognisable form of micro-organism that does not normally occur in Dublin air, and exposing large Petri dishes (diameter 20 cm.) at various heights at the place where contamination was suspected. The organism used was one that formed red pigment, and was intermediate in character between *B. prodigiosus* and *B. Riliensis*. A thick suspension of this in normal saline was thrown into the air at the refuse-heap by means of a spray apparatus, at the rate of a litre per hour. This was kept up for three hours on a day when the wind was blowing in the required direction. Meanwhile six culture dishes were exposed in the perpendicular position, and at heights varying from about 12 to 60 feet above the ground. Afterwards they were closed and the colonies allowed to develop. On four of the six plates red colonies appeared, viz. on those exposed at the heights of 30, 40, 50 and 60 feet, and subculture showed the organisms composing them to be identical with those that had been sprayed. The success of the experiment was rendered the more remarkable by the fact that rain was falling in torrents throughout the three hours' exposure. The author proposed to develop the method and apply it to other problems of the like kind.

PARIS.

Academy of Sciences, April 1.—M. Bouquet de la Grye in the chair.—The new organisation of the study of astronomy and the physics of the globe at the National Observatory of Athens; the presentation of the third volume of the *Annales* of this establishment, by M. Lœwy. The first branch of work developed by M. Eginitis was that of meteorology; at the present time there is one station of the first order at Athens and twenty-one stations of the second order in various parts of Greece. At the same time a systematic study of the geodynamical phenomena of Greece was organised, a network of 550 stations uniformly distributed throughout the whole country dealing with seismic phenomena. The observations from these stations up to the present time have been analysed by M. Eginitis, the results being of great scientific interest. It is clearly shown that there is no connection between the 567 seismic disturbances noted in Greece during the year 1899 and the positions of the moon. Owing to the unavoidable delay in fitting up the astronomical instruments, this branch of work is not so well developed as the others, but aided by the fine climate, valuable observations on meteoric showers have already been recorded.—On the action of human serum on the Trypanosome of the Nagana (*Tr. Brucei*), by M. A. Laveran. It would be supposed that the injection of the serum of an animal naturally immune, such as man, from the attack of the tsetse fly would be without effect in the treatment of animals suffering from the effects of the bites; contrary to expectation, however, human serum has proved to be active. Infected rats and mice, injected with human serum, lost the characteristic organism in from twenty-four to thirty-six hours after the injection. On account of the close analogy between the monkey and man, it appeared to be of interest to compare the action of serum from man and the monkey; the latter serum was found to be quite inactive. The effect of human serum as a preventive against the disease was next tried, but the immunity produced was feeble.—On surfaces of constant negative curvature, by M. Erik Holmgren.—On the heat of solidification of solid ammonia, by MM. de Forcrand and Massol.—A self-recording atmospheric electroscope, by M. G. Le Cadet. An image of the aluminium leaves of the electroscope was projected through a very fine slit on to a revolving sensitised plate. The chief difficulty was due to the extreme fineness of the leaves, this being got over by tilting the box of the electroscope with respect to the optic axis of the apparatus.—On the band spectra

of nitrogen, by M. H. Deslandres. Four distinct groups, characterised by their limits of vibration frequency, have been made out in the spectrum of nitrogen. Cuthbertson has recently shown that the forty bands of the first group can be arranged in thirteen series. Some further regularities in these series are discussed in the present paper.—The cause of the annual period of the aurora borealis, by M. Charles Nordmann. It is known that in mean latitudes the frequency of the aurora possesses a double annual periodicity such that the maxima are at the equinoxes and the minima at the solstices. The author deduces a theoretical explanation of this, which is independent of all hypotheses as to the nature or production of the aurora —On the composition of the lodes of Kersanton, by M. Ch. Barrois. The veins of Kersanton are distinguished from ordinary veins by their composite structure; they have been slowly consolidated under the influence of pneumatolithic phenomena for a very long time. The facts observed are in accord with the theory of M. Michel Levy.—An examination of the meteoric iron of Guatemala, by M. Stanislas Meunier. Analysis showed that the Guatemala iron belongs to the Schwetzite type and is similar to the masses of Descubridora (Mexico, 1780), Werchne-Udinsk (Siberia, 1854) and Schwetz (Prussia, 1857).—The best methods of realising stereoscopic radioscopy, by M. THE EVOLUTION OF MARRIAGE.

The Mystic Rose: a Study of Primitive Marriage. By Ernest Crawley, M.A. Pp. xviii + 492. (London: Macmillan and Co., Ltd., 1902.) Price 12s. net.

THE interest of the scientific problems concerning the origin and development of the marriage relation is perennial. A large part of that interest, though by no means all of it, is derived from the complexity of the factors, the obscurity enshrouding the prehistoric development of the race, and the consequent difficulties attending all investigations into primitive culture. It is forty years since Bachofen published his work on "Das Mutterrecht," to which may fitly be applied that much-abused epithet "epoch-making," for it initiated all really scientific inquiry into the subject. Since then anthropologists, one after another, have incessantly attempted to complete, to correct or to controvert the bold Swiss jurist's conclusions. Mr. Crawley is the latest in the field. He comes well-equipped for his task. He brings psychology to the aid of anthropology, and many of his psychological observations display real insight and throw an important light upon the customs described. His reading has been wide, and his illustrations are generally well chosen. But he rests too often upon second-hand authorities like Ploss and Featherman when the original sources are not difficult to reach, overlooking the possibility that the context of passages used by such compilers may seriously modify their summaries.

Mr. Crawley's theory of marriage is founded upon the universal institution (if it be right to call it an institution) of taboo. He holds that man was probably not always gregarious. At all events, "in early society he had none of the solidarity of clan, tribe, or kin, which is often attributed to him." He was strongly individualistic. As an individual he felt both attraction and repulsion for society. He longed for union with others, and yet he feared their influences. This conflict of emotions gave birth to the complicated system of taboo. It was naturally strongest in the mysterious allurements and repulsions of sex. Next to the craving for food, sexual desire is the most powerful of human appetites. The difference of sex, entailing a difference of physical function, of physical and moral aptitudes and of occupations, inevitably divided man from woman. It produced a sense of strangeness, which behoved caution. That very strangeness, and the consequent shyness, intensified the attraction. All the strength of taboo was therefore concentrated upon sexual relations. From their early days children of different sexes were more or less separated. At puberty (a time of special danger) that separation was emphasised by ceremonies, explained by instruction, and rendered perpetual by the vocations of the two sexes. But separation is impossible. The sexes instinctively seek one another. The puberty-ceremonies, therefore, are a preparation for new and closer relations. Very often they amount to preliminary marriage-rites, espousing the one sex to the other in the abstract, and preparing it for the concrete individual union to be consummated in due time. They do not, however, remove the dangers "responsible for the taboo between the sexes and the various sexual properties of which the contagion is feared." It is the function of the marriage-ceremonies proper "to neutralise these dangers and to make the union safe, prosperous and happy," and, moreover, to bind the contracting parties "so as to prevent, if possible, later repudiation." The object "is not, and never was, to join together the man or the woman, as the case may be, with 'the life, or blood, or flesh of the *tribe*.' There is no trace of this sentimental socialism in primitive society, though there are facts which look like it, no more than there is or ever was a community of wives; marriage is between individuals and is an individualistic act. The mere existence of the egoistic impulse, not to be casually identified with jealousy, is enough to discredit the suggestion; and the tendency of society from primitive animalism upwards has been from individualism to socialism. It is a perversion of history and of psychology as well, to make man more communistic the more primitive he is."

From this sketch of the argument it will be seen that the author arrives at the main conclusions of Dr. Westermarck in his "History of Human Marriage," but by a different route. The wide, if not universal, prevalence of a complicated system of taboo among savages is explained by a primitive individualism. This primitive individualism, if it existed in the full force ascribed to it by Mr. Crawley, must, however, have resulted from the solitary habits of our primitive human and pre-human ancestors. But were their habits solitary? No attempt is made by Mr. Crawley to prove this. Dr. Westermarck certainly attempted it, but his evidence is meagre, vague, often contradicted by his own witnesses, and generally unsatisfactory. The most it could be held to show was that certain outcast races like the Veddahs live ordinarily in pairs or very small communities; while other low races disperse, when food is scarce, into small separate hordes or families to search for sustenance, coming together again at other times. Seeing that mankind, wherever they have been found in a savage state, are, with such exceptions as these, found gregarious, a heavy onus of proof surely lies on those who either assert or assume the race to have been originally solitary. The fear of all contact, to which Mr. Crawley reduces, as its lowest term, the influence of taboo, must have arisen from normal absence of contact, and especially of contact with the opposite sex. But this even Dr. Westermarck's evidence does not prove. Had it been the case, mankind would have speedily perished in the struggle for existence, or been confined, like the higher apes, to limited districts and small numbers. Space to discuss the matter here is wanting. It must suffice to say that the evidence seems to me to point to the development of mankind from a gregarious ape or ape-like being, and that all theories based on a contrary assumption at present lack support.

Among such theories is that of a primitive monogamy. The opposite theory—that of a primitive promiscuity—does not imply perpetual, unbounded, meretricious change of partners. There is some reason to think that mankind, like other mammals, had once a definite breeding-season. If so, the conduct of other mammals subject to "rut" may lead us to suspect that constancy on the part of women at such times was hardly more pronounced

than on the part of men. Nor would such inconstancy be sufficient to produce a pathological condition unfavourable to reproduction, as urged by Maine and Westermarck. As humanity advanced, the organisation of society would compel limitations of licence, which would not necessarily take everywhere the same form. They might very well result in such practices as those of the South Australian tribes (which, despite Mr. Crawley's pleading, bear marks of a transitional character), of many Bantu tribes, of the Eskimo, and of the Seri, perhaps the lowest of all extant peoples. It may be said that this is speculation, since we have no positive proof of a breeding-season, or of the primitive habits of mankind. No doubt it is. But we have to account as best we may or practices not consonant with monogamy. And the fact remains that Mr. Crawley has omitted to study the various forms of the marriage-relation, personal choice among savages, the rights of the husband's kin in the wife and of the wife's kin in the husband, and other subjects the due consideration of which is essential to a correct solution of the problem.

I cannot, therefore, regard "The Mystic Rose" as a complete or satisfactory account of "primitive marriage." I must not, however, be understood to think that it is anything but a valuable contribution to the discussion of the evolution of sexual relations in man. If the author's attention has been absorbed by taboo, it must be remembered that the influence of taboo is an aspect of the theme hitherto greatly neglected. His researches have, consequently, thrown unexpected light on a number of questions which arise out of the strange and what seem to us the preposterous customs of savages. Science has not yet attained the point at which it is possible to identify and unravel all the strands of the tangled web of the history of human marriage. To single out one of the strands for careful and concentrated study helps us appreciably forward. A few more such works, and we may hope to be brought within measurable distance of the goal. E. Sidney Hartland.

CLIMATOLOGICAL ATLAS OF THE RUSSIAN EMPIRE.

Atlas climatologique de l'Empire de Russie. Publié par l'Observatoire physique central Nicolas, à l'Occasion du cinquantième Anniversaire de ses Fondation, 1849–1899. (St. Petersbourg, 1900.)

THIS magnificent atlas has been prepared by Director Rykatchew and published in commemoration of the fiftieth anniversary of the foundation, by the Emperor Nicholas I. on April 1, 1849, of the Central Physical Observatory. The atlas comprises eighty-nine large meteorological maps, together with fifteen graphical tables, which give the best presentation hitherto published of the main features of the climates of the great Eurasian Empire of Russia. Previous to 1849, the meteorology of Russia was prosecuted chiefly by the establishment of first-class meteorological observatories in different parts of the empire, at which eye observations were made hourly by night and by day. It is scarcely possible to exaggerate the importance of these hourly and other results in furthering the development of the science. Indeed, it may be safely predicted that in future developments of meteorology the knowledge thus obtained of the hourly variations from year to year of pressure and temperature, the two prime elements of climate, will always hold a prominent place, more particularly in investigating the relations of meteorology to the secular solar changes.

About the same time Kupfer added considerably to the number of second-order stations, and from this combined system of observation, fuller and more satisfactory climatic data began to be available for different parts of the empire; and when isobaric charts were first published in 1868, no country in the world outrivalled Russia for the importance of the data contributed to the undertaking. Immediately thereafter a phenomenal increase of meteorological stations took place in almost all countries; and here again, with the appointment of Wild as the Director of the Meteorological Department of Russia, the empire took a first position, whether regard be had to the number and quality of the stations or to the wide extent and diversified character of the climates over which they spread.

By the beginning of 1871 this great change may be regarded as having been substantially made. It is with the observations during the thirty years from 1871 to 1900 that the "Climatological Atlas" mainly deals. Quite a large number of stations have been established since 1871, the observations from which have been incorporated and utilised in the preparation of the atlas and the accompanying text by Rykatchew and the collaborators who have written the different sections of this great work.

The atlas gives, for the months and for the year, thirteen charts for each of the departments of pressure, temperature, vapour tension and relative humidity; and similarly five charts for the seasons and the year showing the rainfall, the days of precipitation, and the cloudiness. Additional charts are added representing the annual range of the mean temperature, the absolutely highest and the absolutely lowest observed temperatures, and the absolute range of temperature for each station for the whole time under review. Here it is interesting to note that the lowest temperature anywhere observed on the globe hitherto is $-90^{\circ}\cdot0$ Fahr. at Werkojansk, at a height of 460 feet, lat. 67° 34′ N., long. 133° 51′ E., in the valley of the Yana. On the other hand, the highest temperature was $110^{\circ}\cdot8$, in the arid region of the Trans-Caucasian province. Two charts show the months of greatest and of least precipitation, two the greatest and the least number of rainy days, and two the seasons of greatest and of least cloudiness of the sky. Three charts show the opening and the closing of rivers with ice, one chart the number of days snow lies on the ground, and another the number of days of thunderstorms. Finally, five charts exhibit the paths of cyclones and the types of weather in Russia. The charts, which measure 16 to 27 inches, are printed in colours, showing at once and effectively the geographical distribution of the different elements of climate intended to be represented.

The data showing the mean results of pressure, temperature and other elements of climate, represented on the coloured charts, are given on twenty-seven graphical plates. The usual method is to publish in numerical

tables; but the method now adopted is attended with the great disadvantage of adding enormously to the labour of examining the work critically.

In 1868 the most serious desideratum in Russian meteorology was the large number of undetermined heights among the stations. But shortly thereafter Wild commenced vigorously to make good this great defect, and his successor, Rykatchew, is successfully carrying out this good work. It is much to be desired that in a few years it will be completed. The more important desiderata still outstanding are large portions of northern and south-eastern Siberia.

The new hypsometrical and meteorological data put before us in this atlas are exceedingly valuable accessions to meteorology. For while the broad features of the geographical distribution of pressure and temperature, as previously disclosed, remain substantially the same, yet the fresh data now submitted result in many cases in more accurately defined positions of the isobars, isotherms and wind direction in their occurring changes from month to month.

It is truly a genuine pleasure to the climatologist to use these rectified monthly isobars and isotherms in explanation of the monthly changes in the geographical distribution of snow and rainfall, number of days of precipitation, humidity, cloudiness and other weather phenomena in their all-important bearings on the agricultural and other economic interests of the Russian Empire. Prof. Rykatchew and his singularly able staff are to be congratulated on the successful termination of this great work.

ALEXANDER BUCHAN.

A FRENCH CRITIC OF MAXWELL.

Les Théories électriques de J. Clerk Maxwell. Étude historique et critique. Par M. P. Duhem. Pp. 228. (Paris: A. Hermann, 1902.) Price fr 8.

IN this work the earlier writings of Maxwell on electrical subjects, as well as his "Treatise on Electricity and Magnetism," are discussed. The general attitude is somewhat severe, as may be inferred from the following extract translated from the preface:—

"The different theories of the Scottish physicist are irreconcilable with the traditional theory; they are irreconcilable with each other. . . . At each instant it seems that the result even of his own reasoning and of his calculations is going to drive Maxwell to impossible and contradictory results; but . . . Maxwell makes an embarrassing term disappear, changes an inacceptable sign, transforms the meaning of a symbol; then, having passed the dangerous spot, the new electric theory, enriched by a paralogism, pursues its deductions."

Of the electrostatics in the paper "On Faraday's lines of force," which Prof. Duhem regards as the first of three different theories of statical electricity propounded by Maxwell, his concluding remark is that it is only the semblance of a theory. Maxwell states sufficiently clearly, we should have thought, that his object was not to establish any physical theory, but to point out certain analogies between lines of force and lines of flow.

Of the theory developed in the paper "On physical lines of force," Prof. Duhem writes that it does not even lead to the expression in equations of the problem of the polarisation of a given dielectric medium; this seems to be because Maxwell assumes without formal proof that the function whose spacial differential coefficients express on his theory the electromotive force is identical with the potential of the classic theory; it seems very easy to rectify the omission.

Altogether too much capital is made of Maxwell's unfortunate confusions of sign, and it seems puerile to complain of the use of the popular term "electric tension" where "electric pressure" is required by strict analogy.

Prof. Duhem's objection to Maxwell's interpretation of the various terms in the expression obtained for the magnetic force[1] appears well grounded.

In discussing the third electrostatic theory of Maxwell, as contained in the paper "On a dynamical theory of the electromagnetic field" and in the "Treatise," comments are made on the obscurity of Maxwell's idea of electric displacement and on the confusion caused in the form of the equation of continuity by thinking of a charge of electricity sometimes as a real thing and sometimes as a mere fiction representing the effect of nonuniform polarisation. All readers of Maxwell know these difficulties; most will be disposed to agree with Hertz that if we interpret the word "electricity" in a suitable way, nearly all the apparent contradictions can be made to disappear, rather than follow Prof. Duhem in his *reductio ad absurdum*.

Prof. Duhem contrasts Maxwell's theory of displacement through a dielectric considered as a continuous medium having an elastic constant different from that of pure æther with the theory which regards all the phenomena as due to action at a distance on the analogy of Poisson's theory of induced magnetism. His expression for the electrostatic energy on the latter theory contains a term which is furnished by the surface separating two different dielectrics and which corresponds to the fictitious charge of electricity due to change of polarisation on crossing that surface; consequently he infers that this theory clashes with that of Maxwell. Consideration of the work actually required to charge the conductors in such a case renders it difficult, however, to see how on either theory the expression for the total organised energy can differ from that given by Maxwell. Prof. Duhem then refers to Gouy[2] as having shown that the classic doctrine completely explains the actions observed between conductors and dielectrics by Pellat,[3] among others, and concludes that such actions could not be deduced from Maxwell's theory. In the absence of precise numerical calculation and comparison with experimental results, this inference appears somewhat rash, even if the premisses were correct. Gouy, however, in the paper referred to does not consider the case of two different dielectrics at all. Pellat, moreover, considers the results of his experiments to be in perfect accordance with Maxwell's theory; he points out, however, that as his calculations of the effective forces on the surfaces of conductors and dielectrics are deduced from the variation of the electrostatic energy, his experimental results, as well as those of Quincke, may be explained without accepting Maxwell's

1 "Scientific Papers," vol. i. p. 463.
2 *Journal de Physique*, 3e série, t. v. p. 154, 1896.
3 *Annales de Chimie et de Physique*, 7e série, t. v. 1895.

theory and thus do not serve to establish it. (The simplicity and directness of Pellat's theoretical investigation seem noteworthy when compared with the discussions of Gouy and of Larmor;[1] in each of the latter some of the apparent forces have to be explained away, and they appear to contradict each other. It may be that in such discussions too much importance is at present assigned to Maxwell's stress-system in the absence of more definite knowledge concerning the transmission of force between æther and matter, if the use of such a phrase is permissible.)

Prof. Duhem points out that Maxwell, in obtaining his first estimate of the velocity with which electromagnetic waves are propagated,[2] confounds Lamé's coefficient of rigidity with one of his own, which is really double the former, and that on correcting this mistake a velocity is obtained which exceeds that of light in the ratio of $\sqrt{2}$ to 1. This work of Maxwell's is, however, generally regarded as containing only the germ of a theory of light and as indicating that the two velocities concerned are of the same order of magnitude.

The author concludes by lauding the electrodynamic theory of Helmholtz, which he regards as satisfactorily reconciling the electromagnetic theory of light with the ancient theories of electricity and magnetism.

It is surprising to find no reference whatever to Larmor or to H. A. Lorentz in the historical sketch of this branch of the subject.

Although some of the mistakes pointed out by Prof. Duhem are real and important, the view taken throughout, as will be gathered from the above, appears a very narrow one.

W. McF. ORR.

OUR BOOK SHELF.

Clinical Pathology and Practical Morbid Histology. By J. Strangeways Pigg, M.A. Second edition. Pp. 107; 5 plates and 6 figures. (London: Strangeways and Sons, 1901.) Price 5*s.*

THIS is a small interleaved handbook for use in the laboratory, dealing with the different methods employed in examining blood and other normal and pathological fluids and morbid tissues.

The descriptions of the various methods referred to are brief and concise, and the steps of each operation are tabulated in exact sequence, with perhaps the exception of 24, D, where steps 6 and 5 should obviously be transposed. Objection may be raised to such an arrangement as being too dogmatic and allowing no scope for individual ingenuity, but, on the other hand, those who have to deal with large classes of students, to whom the book is chiefly directed, will agree that some such method is absolutely necessary if one would instil the principles underlying good technique.

The general "get-up" of the book is good; there are very few printers' errors save an occasional missing letter at the end of a line, or the interpolation of a letter from another fount of type. "The illustrations," we are told, "are diagrams only," a description obviously applying to those of apparatus and urinary sediments—which latter, by the way, would have been more useful had they been bound up in somewhat closer proximity to the letterpress relating to them—but hardly fair to the two coloured plates of blood-cells. These are, in spite of their accuracy, beautiful and artistic, and reflect nothing but credit on artist and lithographer.

[1] *Phil. Trans.* 1897, A. p. 248.
[2] "Scientific Papers," vol. i. p. 500.

The methods set out in the text are, for the most part, well chosen and well described; those dealing with morbid histology are, however, by far the most successful. In blood work, we notice, the author recommends Cabot's "two-cover-slip" method of spreading films—a method which in the hands of experts yields, perhaps, 10 per cent. of stainable specimens—and quite ignores the simpler method introduced by Manson, in which gutta-percha tissue or a piece of cigarette paper is employed.

We notice, too, in the preparation of cover-glass films from pus or sputum, that extremely dirty and slovenly method of pressing out a small portion of the material between two cover-glasses and then sliding them apart, is given as the usual method. We hope that this is not the universal practice in Cambridge laboratories.

The sections dealing with bacteriological methods and urinalysis are certainly disappointing—in the latter the methods are few in number and, in our opinion, not always happily chosen, whilst fuller indications of the fallacies which attend some of the tests would have enhanced their value. In that portion dealing with bacteriological investigations, many of the methods might find favour in the clinical laboratory, but would certainly be *taboo* in the well-regulated bacteriological laboratory. We notice, too, that the author invariably uses *Carbol*-gentian-violet in staining by the method he terms Gram's; it is true the actual stain is easier to prepare, but its results are decidedly inferior to those yielded by the Anilin-gentian-violet originally described by Gram.

As we have before mentioned, the book is intended for the medical student, and as such is of distinct value, a fact sufficiently evidenced by the success with which the first edition has met

The Balancing of Engines. By W. E. Dalby, M.A., B Sc. Pp. xi + 283. (London: Edward Arnold, 1902.) Price 10*s.* 6*d.* net.

THIS work is of a character which can be studied with interest. It deals with a subject of great importance to mechanical engineers, and one which is coming more and more to the front in the design of high-speed engines and machinery.

Prof. Dalby is the author of several papers dealing with this important subject, read before the Institutions of Naval Architects and Mechanical Engineers; these papers are largely drawn upon in the present volume.

"The main object of the book is to develop a semi-graphical method which may be consistently used to attack problems connected with the balancing of the inertia forces arising from the relative motion of the parts of an engine or machine." This we learn from the preface, and, what is more, it requires nothing but the knowledge of the four rules of arithmetic and good draughtsmanship to apply satisfactorily the methods so well described.

The balancing of the working part of locomotives has always been treated from different points of view, and the practice of a particular drawing office largely governed the result; in fact, not many years ago an eminent locomotive engineer looked upon the balancing of his locomotives as an unnecessary addition to their weight.

Chapter iv. deals with this very important subject in a clear, concise and practical manner, and even only for this one chapter all interested in locomotive design should possess this volume. The author advises that those interested in locomotive work should begin chapter iv., after working the examples of arts. 48 and 49, progress being tested by working the exercises at the end of the book.

The treatment is simple, several types of Lancashire and Yorkshire Railway Company's locomotives being taken as examples, and little thought will be necessary to carefully follow the threads of the argument. The experimental apparatus described to illustrate the

various problems of locomotive balancing is very interesting, appearing to thoroughly fulfil the conditions.

Prof. Dalby has produced a book useful alike to the mechanical engineer and the student. N. J. L.

Guide to Italy. Pp. civ+352+4. Price 10*s*. net.
Guide to the Western Mediterranean. Pp. xxvi+238. (London: Macmillan and Co., Ltd., 1901.) Price 9*s*. net.

IN adding one more series of guide-books to those already in existence, the publishers have struck out in a somewhat new line by making conciseness their most important feature. The overworked professional man, who has little time to read up lengthy descriptions, will here find, condensed into a smaller compass than has previously been done, the most important points to be looked out for on his proposed journey. The authors of these books have been remarkably successful in condensing so large an amount of information into them.

The "Western Mediterranean" is divided into sections dealing respectively with Lisbon, Andalusia, Morocco, Algeria, Malta, Naples, the Riviera, the Balearics, and other ports and districts of interest. In "Italy" a different and novel order has been adopted. The book opens with articles on Italian life, art and architecture by "O. B." and other well-known writers. Next comes a description of routes *only*, without lengthy descriptions of towns; lastly, the towns of Italy are described in alphabetical order. The advantages of this method may not, perhaps, impress the reader at a first glance, but as soon as he is accustomed to the new order of things he will become converted to the belief that the system effects a considerable saving of time and trouble and is most convenient. Hotels are enumerated in a list by themselves; in a future edition the authors might with advantage make an effort to give fuller information under this head, especially in reference to tariffs. There are also a few minor points on which opinions may differ. Most Italians know an "Inglese" fast enough and do not take every foreigner for a Frenchman (p. xii.); in the vocabulary (p. xvi.), "entrate" is a more familiar equivalent for "come in" than "avanti"; and if the authors of "Italy" are *really* right as to the situation of Virgil's tomb (p. 147), Neapolitan guides and cab-drivers have been wrong for many years. The maps are excellent.

Outlines of Electrochemistry. By H. C. Jones. Pp. vi + 106. (New York: The *Electrical Review* Publishing Co., 1901.)

THIS is an exceedingly interesting book. The title is, perhaps, a little misleading. To our mind it would be better to call it "Physical Foundations of Electrochemistry," or some similar title. There is an inclination among writers of electrochemistry to treat the subject entirely from the physical standpoint, hence many books on the subject lack breadth of treatment. The present book, as the author explains in the preface, is a republication of papers which originally appeared in the *Electrical Review* (New York).

Chapter i. deals with osmotic pressure in a very clear and lucid manner. Chapter iv., on the "newer theories of electrolysis," is very ably written, and here Mr. Jones, in explaining the theory of the electrolysis of water containing acids, alkalis or salts in solution, adopts the theory of Le Blanc, which looks upon the electrolysis of water as being a *primary* and not a secondary reaction. Most writers explain the electrolysis of water as being of a secondary nature, due to the presence of the acid or base in solution. According to Le Blanc, it is entirely a question of the decomposition value of the water, and of the salts, acids or bases in solution. In an aqueous solution of an acid, for example, it is simply a question whether the ions of the acid or those of the water will the more readily give up their electrical charges, it being assumed that pure water is slightly ionised.

Chapter vi., which is divided into two parts, deals with the "conductivity of solutions," and a very interesting lecture experiment, due to Noyes and Blanchard, for showing the different conducting powers of various electrolytes, is described. A good deal of attention is devoted to the dissociating power of different solvents, especial stress being laid upon the dissociation of electrolytes in alcohol. Mr. Jones does not, however, refer to the fact that certain inorganic salts are considerably ionised when dissolved in pyridine. In this connection it is interesting to notice that quite recently Kahlenburg has succeeded in depositing lithium in the metallic form, from the solution of its chloride in pyridine.

Mr. Jones is to be congratulated upon having presented us with a very readable and scientifically written account of the foundations of electrochemistry. We notice that the author is engaged upon a work on physical chemistry, the production of which we await with interest.

F. M. P.

Outlines of Botany. By R. G. Leavitt. Pp. 272. (New York: American Book Company.)

THIS book has been compiled for use in high schools and is based on Asa Gray's "Lessons in Botany," an abridgment of his well-known standard work on plant morphology. The author points out that he is not in agreement with the strong ecological bias developed in so many recent American text-books, and that he has endeavoured rather to develop the study of structure and form, and also to emphasise the physiological factors which control plant life. This view will be endorsed by many botanists.

The method adopted is to suggest a series of practical studies, each being followed by an elaborated theoretical discussion. The principle involved of setting the student to learn by direct observation depends firstly on the student and secondly on appropriate treatment of the subject. For advanced students such a course might be admirable. But for students at high schools there is neither the requisite time nor training required for such investigations; for these introductory lectures are absolutely necessary. Then again, as regards his treatment of the subject, one must entirely differ from the author. The first chapter, dealing with seeds and seedlings, will illustrate the objections to be raised. Beginning with the gross features of the castor bean, lupin and maize, the author next proposes a series of physiological exercises—*e.g.* the nature and location of food reserves; absorption of oxygen, production of carbon dioxide and heat evolved in germination; geotropism and development of chlorophyll. He then returns to morphology to give a brief summary of special morphological features. It will be observed that on the one hand the training to be gained by a well-balanced and varied series of anatomical exercises seems to have been overlooked, for the castor bean does not offer a favourable object for a first investigation, and at least eight or ten seeds should be examined. On the other hand, the physiology is too varied. What teacher with practical experience does not know the many difficulties and pitfalls which attend even simple experiments? What success may be expected for a young and inexperienced investigator who attempts these broadly-extending exercises, with the help of descriptions which are often extremely vague? Throughout the chapters dealing with the flowering plant there is the same paucity of development and want of judgment in choosing anatomical exercises. The book contains a cryptogamic course which is somewhat superficial, and closes with two unsatisfactory chapters on anatomy and physiology.

LETTERS TO THE EDITOR.

The Permeability of Iron Alloys.

In a paper in the last number of the *Proceedings* of the Royal Society, Prof. Barrett refers to the increased permeability conferred on iron by alloying it with aluminium, and suggests an explanation on the supposition that the aluminium would remove traces of oxygen from the iron.

Some seven years ago, in the course of a series of measurements on the magnetic properties of iron alloys, I found that aluminium, phosphorus and arsenic decreased the coercive force and hysteresis loss very considerably, whilst aluminium very largely increased the permeability—the others less so. Silicon produced little effect, but probably slightly improved the iron. On mentioning this to my colleague, Prof. Arnold, he at once pointed out that these elements are just those which increase the size of the crystals in iron. Annealing, which also improves permeability and lessens hysteresis, also increases the scale of the crystals. It is probable, therefore, that the increase of permeability due to these substances is a secondary effect due to the increased size of the iron crystals. A foreign substance might be expected to act deleteriously in two ways: (1) by occupying space better filled by iron, (2) by combining with iron and forming a less magnetic chemical compound. Phosphorus and silicon would act in both ways, aluminium in the first only, which might account for a larger difference between its indirect favourable action on the iron crystals and its direct deleterious action. It would be interesting if investigators in this direction would try to correlate their permeability measurements with the results of microscopical analysis as well as chemical. W. M. Hicks.

University College, Sheffield, April 10.

Reform in Mathematical Teaching.

Some of Prof. Perry's followers seem to me to miss a point which he realises clearly—viz. that the key to the whole position is in the examination system.

(1) The strength of the present system is very great. An impending examination converts the teacher from an enemy of the idle and refractory pupil into an ally—to the comfort of all parties. The success of his pupils at examinations gives a teacher some return for his labour; otherwise he would have to comfort himself by hoping that Kipling's great lines, "Therefore praise we famous men," might some day in some degree apply to him. The realised hope would be worth ten thousand times the immediate return, but hope deferred is discounted at very heavy rates.

(2) The present system might be very much better. Examining work is often badly paid; in the main and in the long run, bad pay means bad work. Thring said that you might have one generation of martyrs, but the second would be cheats.

The band of fossil examiners, each with his fossil syllabus, does much more harm than Procrustes. A is clever, but he must not go beyond the syllabus; B is slow, but he must be bustled along and got through the course somehow.

The fate of anything new or fresh is pretty sure. There is a Cambridge yarn about some one who set his favourite question, "Define a differential coefficient," but instead of getting the expected three or four lines of cram, he got the substance of five or six pages of Harnack's new German book on the calculus. He rose to the occasion and promptly marked it 0.

(3) But written examinations have inherent and inevitable defects, clearly indicated by Dr. Lathom "Examinations considered as a means of selection." The old style of question, which was rather reproduced than parodied by the famous "Very small elephant whose weight may be neglected, and whose coefficient of friction was $\sqrt{7}-\sqrt{3}$," may be replaced by "The relation between the weight and length of tusk of an elephant being represented by the equation $W=Al^3+Bl+C$," and so on . . . but a system of written examinations based on the new model would in the end be like unto the first.

The following axioms are put forward in the hope that they may be condemned as truisms:—

(1) Examinations are not to be multiplied beyond necessity.

(2) No examination is entitled to any confidence in which teachers or persons in close touch with the teachers have no part.

(3) *Viva voce* examinations are essential if weight is to be attached to the results of a single examination.

It would be most interesting if Prof. Perry, who has influence and persuasiveness, could arrange an experiment.

Get answers to a paper from a dozen candidates, good and bad mixed, have facsimile copies made, and submit them to twenty or so competent examiners. The discrepancies in the marks would, I think, be surprising.

If the examiners adopt the received plan of cutting each question into several bits and giving marks for each little bit, they will get results more concordant and more entirely out of relation to common sense or real life. C. S. Jackson.

Woolwich.

There are two places in Prof. Perry's letter appearing in your issue of March 27 in which he mentions schoolmasters in terms of, in the one case praise, in the other blame. The first passage is where he congratulates the "reformers" "on having with them the good wishes of every thoughtful teacher of the whole country," but in the last passage he expresses the conviction that we shall "not very long remain in the foremost files of our time if we depend upon the schoolmasters." I hope that teachers are good for more than mere good wishes, and I think Prof. Perry will find that the reform he laments as scarcely within sight has not only begun, but is actually bearing fruit in the place in which, though the subject of controversy, the noise of the conflict is heard least—the schoolroom. Schoolmasters, like others, move with the times, and the "conventional schoolmaster" is a much rarer bird than the conventional examiner or the conventional inspector. I suppose syllabuses and text-books are a necessity still, but the competent teacher of mathematics needs not to be bound by anything of the kind. Personally, I see no necessity for this ideal text-book one hears about which is to replace Euclid, and those who caricature him; we are better without a text-book at all. Let a master be engaged capable of making his own syllabus for his own pupils, and give him a free hand to introduce modern geometry, differential calculus, &c., as he sees fit; such a man will welcome the appreciation of a competent inspector, himself a mathematician and, beyond that, a successful teacher of mathematics. As I have already hinted, reform in the schoolroom proceeds as rapidly as examiners will allow, rather more so in fact, for I know that many boys learn much that no examination they have been in for, or are likely to take, tests. My own work is in such a small way that I do not care much to bring it forward, but I must confess to periods of guilty satisfaction when I have robbed time from examination teaching and introduced boys, much to their interest, and I feel sure profit, to such things as coaxal circles, theory of inversion, cross ratios, and fundamentals of the integral calculus. Let the mouse help the lion!

I feel sure Prof. Perry and his fellow reformers—if they will find out what is being done on the spot by the teachers, or if the latter have as yet shrunk from any sort of attempt at reform, what their wishes and opinions are—will find convention at least as hateful to the teachers as to themselves. Of course, I am not speaking, as I am not qualified to speak, on behalf of those who form what I may term the "aristocracy" of the teaching profession; I myself and my teaching friends are mostly engaged in the small schools, large in number, situated in industrial districts, where the endowed school fights for an existence with the "technical" or even the higher-grade Board School, where boys leave between fourteen and sixteen, at the latter of which ages they are supposed to have the groundwork on which a knowledge of engineering can be built up. Yet to these Euclid must be taught. Of course, as a matter of fact, Euclid is not taught to them; they pass examinations in a subject that goes by that name, the satisfaction I personally have felt being in the reports of examiners, who, intending to reprove, have written, "the constructions and principles of proof were well known, but the wording of Euclid was not adhered to, and some points in the proofs were omitted. The riders were well done." In these schools, "practical plane and solid geometry" is a subject taught throughout; and there is many a germ which only requires a little encouragement to bear great fruit. I think that the power behind the reformers

may be even more potent than it is reckoned. With associations growing in influence, and the great facilities afforded for exchange of ideas, the body of teachers is very rapidly increasing in strength, and this reform in the teaching of mathematics, together with many another much-needed reform, is perhaps much more in the immediate future than is thought. At any rate, if the bow and arrow is still the official weapon, the use of the magazine rifle is being secretly taught, and we school teachers look forward with no misgivings to that great fight. Prof. Perry sees ahead for our people, rather we are "spoiling for it," for with it will come our freedom!

FRANK L. WARD.

1 Macdonald Place, Hartlepool, March 29.

Rearrangement of Euclid Book I., Pt. i.

IN answer to Prof. Lodge's letter I should like to say that we have for some time followed much the order he suggests. Euclid's order unnaturally separates propositions which should come together, *e.g.* I. 4, 8, 26, and is, therefore, a serious hindrance to a clear grasp of the subject-matter as distinct from mere exercise in logic.

The following order—substantially that suggested by Prof. Lodge—seems natural, and we have certainly found it work very well in practice.

(1) The propositions on angles, viz. 13, 14, 15, 27, 29, 32, cor. 2, 32. At this stage logical deduction from definitions and axioms is difficult and, to a boy, unconvincing. The following proof of I. 32 cor. 2 is convincing, at least: "If a man walks right round a rectilineal figure (starting and ending at a point in the middle of a side), he turns once round. Hence the exterior angles, which are the angles through which he turns, are together equal to 4 right angles." Similar proofs of 27 and 29 are equally convincing. Any attempt to analyse these proofs into the axioms on which they depend seems to me at this stage foolish; it is work for a highly trained and speculative mind, not for a boy.

(2) Triangulation, I. 4, 8, 26.

These are, I think, best presented as the outcome of experience passing into intuition, and as special cases of the general fact that three data are necessary and sometimes sufficient to determine a triangle. The special case of right-angled triangles with hypotenuse and one side given should be added and proved deductively from I. 5.

The rest of Book I. consists of exercises on these fundamental propositions:—Properties of a single triangle, I. 20, 5, 18, 6, 19; loci; quadrilaterals; areas. The order in which these last three subjects are taken is immaterial.

A special advantage of this arrangement is that it makes it easy to combine practical with theoretical work. It was, indeed, from the attempt to do this that we were led to follow this order, but even in purely theoretical work it has proved a great gain.

As to the omission of "constructions" from the deductive course, we agree—they are properly treated as exercises.

As to the effect of this change on real progress we have no doubt. As to examinations, we hope that they will before long (1) permit freedom in the order of propositions, (2) diminish bookwork and insist upon riders and practical work, as some, indeed, already do.

It seems illogical, but even in deserting Euclid's order we adhere to his numbers. The constant reference to cardinal propositions is a great help to thoroughness and clearness of knowledge, as well as to ease of questioning and answering. Probably no one will ever succeed in fixing fresh labels on to the propositions, and for the present at least we find the old ones useful, though they are to our boys quite arbitrary.

W. C. FLETCHER.

Liverpool Institute.

I QUITE agree with Prof. Alfred Lodge as to the order of propositions he proposes, which is practically the order I adopted in my "Foundations of Geometry." But he does not in his letter refer to what seems to me the chief reason for it, which is that the elementary geometry of straight lines and angles should precede the geometry of plane surfaces, including any propositions about areas. And to carry out this idea, the fundamental propositions which Euclid gives so badly in his XIth. book (props. 1–9) ought to be taken before such propositions as his I. 35 and 36. On the other hand, there are important propositions in the XIth. book, notably prop. 10 (if this is not included in the definition of parallelism) and props. 20 and 21, which come properly in what Prof. Lodge calls the first part of Book I.

By the way, I may mention that it seems to me illogical to prove I. 27, as Prof. Lodge does, by a simple "which is impossible," and to refer I. 29 to "Playfair's axiom." Neither proposition is nearer *a priori* truth than the other, and it is just as easy to disguise the difficulty, if you wish to do so, in either case.

EDWARD T. DIXON.

Racketts, Hythe, Hants, April 14.

WE have had the following arrangement of Euc., 1–32, in use for three years with more than two hundred pupils. 13, 14 (from the definitions); 15; 32, cor. 2, 32, 16, 17; 23, 8, 9; 4, 10. Locus of a point equidistant from two given points. 11, 12, 5; 26, 6. Locus of points equidistant from two intersecting straight lines.

This gives fourteen propositions; thirty-seven more complete all the plane geometry of Euc. I.–VI. and XII. required in mathematics or science. We have no superposition "proofs"; they merely obscure obvious truths. Parallels by superposition have been found beyond the capabilities of beginners. Why not alter the definition? At present it gives the least obvious property of parallels.

A caution to the professors who are teaching us how to teach. We are seeking a system of geometry suitable for boys of ten, and the most logical method is not necessarily the best; it is better to separate 4, 8, 26 by examples of their use and to leave the remaining case for trigonometry. Again, an ideal course must be inventional, and must grow out of practical work; therefore it must introduce problems as early as possible: a beginner should not be allowed to quote a construction which he cannot perform. Is not the demand for a purely theoretical course due to a desire to use 1, 9, in proving 1, 5, whilst retaining Euclid's proof of 1, 8?

T. PETCH.

Leyton Technical Institute, April 14.

IN reply to the appeal of Prof. Alfred Lodge for opinions with reference to his proposal to alter the sequence of Euclid's propositions by introducing those relating to parallels at the earliest possible stage, permit me to express what I hold to be insuperable objections to his proposed innovation.

Whatever other objections may be raised to Euclid's sequence of propositions, it at any rate has this distinguishing merit, that it separates the propositions (I. 1–28) which are independent of the postulate of parallels from those which are true only when that postulate is admitted. To obscure this distinction, as, for instance, by treating props. 16, 17 as corollaries of prop. 32 and so appearing to depend on the postulate of parallels, would to my mind, especially now that the non-Euclidean geometry of Lobatchewsky and others is an established part of mathematical science, be a distinctly retrograde step.

Further, this innovation is not in the least necessary to secure Prof. Lodge's object (with which I entirely sympathise), namely, a better and more natural grouping of the propositions about triangles.

For this purpose all that is necessary is to add I. 16 to the three (13, 14, 15) with which he proposes to begin. This proposition may at once be proved as follows:—

The triangle being A B C, the side B C produced to D and E the mid-point of A C, turn the triangle A E B about E until E A comes on E C and A on C, then E B comes to a position E F in the same straight line as B E, and since B E F, B C D meet in B. they cannot meet again, so that F lies on the same side of B D as A [N.B., here comes in the difference between plane and spherical surface geometry], and E C F or the angle A is less than the exterior angle A C D.

This proved and I. 17 as its corollary, the propositions about a single triangle and those about the comparison of triangles easily fall into a simple and natural sequence and grouping.

Shanklin, April 12.

ROBT. B. HAYWARD.

Winter Phenomena in Lakeland.

THERE being no record within my knowledge as to whether holly and ivy are starch-trees or fat-trees, *i.e.* as to whether their wood-starch disappears or otherwise in winter, a strict watch was set upon the phenomena. During the months of December, January and February, sections were taken at

intervals of the twigs and smaller branches of these trees, and their content in starch was carefully tested and observed. The general result was that the ivy is a decided starch-tree, inasmuch as at no time during the winter was its wood found free of starch or anyway nearly so. No doubt, as compared with summer, there was a great diminution of this substance, many of the medullary ray cells being completely empty of granules, and moreover, *e.g.* on January 18, only about one-quarter of these cells were stored with starch, and even this gave a reddish-brown tinge to iodine, as if amylodextrin was intermixed therewith. As regards the holly, there could be no question that the amylaceous reservoirs of its wood had suffered a still more serious depletion. Nevertheless, they were never found completely void, a more or less considerable accumulation of starch granules being readily distinguishable along some portion of the medullary rays; the pith, too, was never empty (that of the ivy was found invariably depleted). It may be added that in both cases starch was completely absent from the bark during the winter months.

The overthrow by the boisterous gales of the departing year of a crab-apple that was perched aslant on a sharp ridge of rock afforded an opportunity for observation of the root appanage of this tree. The wood of the root contained a considerable amount of starch, but none was found in its bark. The alcoholic and aqueous extracts of the latter proved very rich in phloridzin, the reactions thereof being yielded with eminent distinctness and beauty, and the phloretin prepared from it indicated by its behaviour in alkaline solution with nitroprusside of sodium that it was a fatty aromatic ketone. Phloroglucin was detected in the wood, but none in the bark.

Whilst exercising on the hills on January 19, numerous faded and embrowned brackens were seen which a week or so previously had been overlaid with a thick mantle of snow. The fronds of one of these were incinerated, and the crude ash was found to contain no less than 43·6 per cent. of silica, also 13·2 CaO and 0·8 phosphorus (or 1·8 P_2O_5). This enormous amount of silica is all the more remarkable, inasmuch as in August the ash of the fronds contains only about 9 per cent. of this constituent and that of the stem about 7 per cent.—the difference is doubtless to be attributed to the very considerable diminution of the soluble salts, and not of the lime, during the course of autumn. In this case, as in that of all calcifugous species, a strong proportion of lime in the young and vigorous frond would offer a serious obstacle to the presence of a considerable quantity of potass. Thus, on June 3 the amount of potass and soda in the ash is somewhere about 32 per cent., in August 27 per cent., and in late autumn about 2 or 3 per cent. The lime, on the other hand, fluctuates from about 6 to about 13 per cent. only, and thus while in a great many leaves the autumnal deficit is, so to speak, covered by lime, here in the case of the bracken it is refunded by a lavish plethora of silica. The general inference is that the frond, having been utilised as a support for the reproductive parts (sporangia), the strain thereby involved leads to a very advanced condition of decay, whence a tremendous drainage of silica towards the organ. Perhaps it is this very faculty of remaining decayed without disfigurement, encased in silica, that is one of the causes why abundant remains of ferns are found in the fossil state.

Patterdale, Westmorland. P. Q. KEEGAN.

The Species Problem in Corals.

MAY I direct the attention of your readers to an exhaustive article, dealing specially with "species" among the reef-corals, by Prof. Döderlein in the current number of the *Zeitschrift für Morphologie und Anthropologie*? It is somewhat hard to find myself there blamed for continuing to use the word "species" in relation to a group in which it is totally inapplicable, for I laid the whole subject before the Linnean Society a year ago. I stated the difficulty and suggested a provisional alternative method of designating specimens. I carefully explained that I was proposing a method of work in order that we might discover the true species by gradual arrangement of the variations. In the autumn of the same year I made a brief statement at the International Congress of Zoologists in Berlin, but the report has not yet appeared; and again, later in the year, I read a paper before the Cambridge Philosophical Society. This has appeared in the last number of the *Proceedings* of that Society under the title "On the Unit of Classification for Systematic Biology."

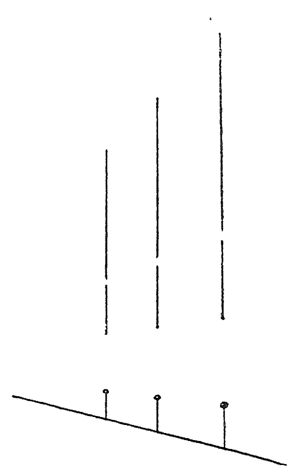
It will be noticed that while Prof. Döderlein discusses the general problem very fully, he makes no practical suggestion as to how to designate the different forms for reference. I, struggling with nearly a thousand foolscap pages (dealing with three genera) for the "Catalogue" of the Great National Collection of Corals at South Kensington, was compelled to invent some way of labelling them. But before finally adopting it, I sought the advice of many of the leading zoologists and botanists within reach. HENRY M. BERNARD.

Clapham, S.W., March 21.

Sun Pillars.

ON January 19, 1901, during zero weather at Winnipeg, Manitoba, the fine icy particles which floated over the city as a cloud at 11 a.m. gave a halo round the sun with two mock suns to the right or left at the same altitude as the sun, and above the halo an inverted arc of about 120° showing prismatic colours. There was a good deal of wind at the time.

At night the wind dropped and the air became very still. The haze of icy particles descended, and in the middle of the night its illumination by the strong arc lamps of the city gave a column of light, comparable to a sun pillar, extending above each lamp to a height estimated at 300 feet. A striking feature of the phenomenon was the perspective effect, the columns diminishing in apparent height in such precise proportion to the increasing distances of the street lamps that it was evident the upper surface of the cloud of particles was truly horizontal. At this time the vertical columns of light were also visible below the lamps and extended to within a few feet of the ground. A few hours later, viz. at 4 a.m. January 20, the lower ends of the columns were more than 60 feet from the ground, and therefore far above the lamps.



They extended to a height of about 300 feet, as judged by the distance of the nearest lamp and my elevation above the ground, which was about 60 feet. A narrow rift extended horizontally through the cloud, breaking each column of light into two parts. The figure is re-drawn from a rough sketch made at this time of the columns above three, only, of the numerous arc lamps.

The slight haze of minute icy particles which is common in zero weather is, I believe, called *poudrette* in Eastern Canada

VAUGHAN CORNISH.

Swarm of Velella.

ON a former occasion while sailing in the Mediterranean I have noticed the abundance of this beautiful Hydro medusa, usually known as the "Portuguese Man-of-War," sometimes distributed over the surface of the sea, but never in numbers such as have been stranded along the northern shores during the past few days.

When taking my usual morning bathe at Mentone on April 5, I plunged into a living mass of these Siphonophora, which extended many yards from the shore. It was about the same on the 6th, when I gathered a number and preserved them in formol (5 per cent. from the 40 per cent. solution). Since then the shore has been literally strewn with them, a very disagreeable odour being emitted. At Bordighera yesterday and here to-day, nearly fifty miles from Mentone, their dried remains strew the shore and appear to be well preserved, though, of course, minus their beautiful colour. We have had no strong south winds, and I cannot see how to account for so remarkable a shoal. ISAAC C. THOMPSON.

Alassio, April 9.

Resultant-Tones and the Harmonic Series.

THE following method of recovering, by inspection of the harmonic series, the position of the differential resultant-tone of the first order for any given musical interval has occurred to me, and, as far as I have been able to learn, has not yet found a place in the text-books on musical acoustics which are in most common use. I therefore venture to hope that a brief statement of it may gain admittance to your columns and be the means of saving some time and trouble to students of the subject.

The harmonic series up to No. 10, with the order of each number placed below it, may be written thus:

C	C′	G′	C″	E″	G″	(B″♭)	C‴	D‴	E‴
1	2	3	4	5	6	(7)	8	9	10

the brackets of course indicating that No. 7 is not identical with the seventh note of the diatonic scale. As the "vibration numbers," or "frequencies," of these harmonics are proportional to their respective order-numbers, these latter may, for the purpose in hand, be treated *as if they were the vibration-numbers* of the corresponding harmonics. Hence the difference between any two order-numbers will give the vibration-number of the resultant-tone for the interval formed by the two corresponding harmonics, and the position of the resultant-tone in the harmonic series will thus be at once assigned.

Successive application of the above method to a series of intervals gives the following results:—

Minor tone D‴ – E‴, $10-9=1$. Resultant tone C, 3 octaves and a major tone below the graver primary.

Major tone C‴ – D‴, $9-8=1$. Resultant tone C, 3 octaves below the graver primary.

Minor third E″ – G″, $6-5=1$. Resultant tone C, 2 octaves and major third below the graver primary.

Major third C″ – E″, $5-4=1$. Resultant tone C, 2 octaves below the graver primary.

Fourth G′ – C″, $4-3=1$. Resultant tone C, a twelfth below the graver primary.

Fifth C′ – G′, $3-2=1$. Resultant tone C, 1 octave.

Minor sixth E″ – C‴, $8-5=3$. Resultant tone G′, major sixth below the graver primary.

Major sixth G′ – E″, $5-3=2$. Resultant tone C′, fifth below the graver primary.

Octave C – C′, $2-1=1$. Resultant tone C, coincident with the graver primary.

Ninth C″ – D‴, $9-4=5$. Resultant tone E″, a major third *above* the graver primary.

In order similarly to treat semi-tones, sevenths and other dissonant intervals, it is only necessary to include higher numbers of the harmonic series, and the method is evidently as applicable to summational as to differential resultant-tones.

MARGARET DICKINS.

Tardebigge Vicarage, Bromsgrove, April 5.

Municipal Meteorology.

IN your notes in NATURE for April 3 (p. 518) you mention Dr. H. R. Mill's observations as to the length of the February frost, the period at Torquay being reported the shortest, viz. nine days.

I think it should be pointed out that for scientific purposes the Torquay temperatures should be treated with much caution, as those of an extremely sheltered spot, viz. Cary Green. Up to last year Torquay had two observing stations; but one of them, viz. that at Chapel Hill, was given up. On moving the adoption of the report advising, among other things, the discontinuance of the said station, a member of the Town Council very honestly remarked that "the range of temperature at Chapel Hill was greater than that at the Princess Gardens, and it was *more satisfactory for the town* to have as small a range of temperature as possible"! (*Western Morning News*, March 6, 1901). According to the last meteorological report, the temperatures are still taken at one of the old stations, viz. Cary Green. The differences between Chapel Hill and Cary Green were often considerable, *e.g.* on March 18, 1900, Chapel Hill 23°·9, Cary Green 27°.

A Gall-making Cynipid Fly in Jamaica.

THE Hymenopterous gall-makers of the family Cynipidæ, though widely distributed over the earth, have seemed to be totally absent from the West Indies, somewhat to the astonishment of entomologists. However, in February, 1892, Mr. W. Harris sent me a gall on *Bidens reptans*, collected by Mr. Nicholls at Cinchona, Jamaica. The gall was a large oblong swelling attached to the stem of the plant, and contained many cells. Unfortunately, I was not able to breed the flies, but I secured some immature fragments, which sufficed to show that they were Cynipidæ. Mr. W. H. Ashmead, to whom I submitted my notes and sketches, is of opinion that the genus must be Aulax or allied thereto. Although it is impossible to determine the species, it seems desirable to call attention to the occurrence of this gall-maker in Jamaica; and perhaps one of your West Indian readers will be able to supply us with complete information.

Criticism of "The Great Persian War."

MAY I call attention to one or two points in your critic's treatment of my work (p. 434)?

(1) Your critic says that at Thermopylæ "the mound and the Phocian Wall are the only debatable points."

I may mention that, among many other debatable points, some persons who have examined the pass have located the fight at the West gate.

(2) Your critic is apparently not aware that the site of Trachis is uncertain. Two sites at some distance from one another have been proposed.

(3) Of Aphetæ he says, "it is hard to reconcile Mr. Grundy's situation with the remark of Herodotus, that the wreckage of the first sea-fight drifted *out* (the italics are your critic's) to Aphetæ, which is badly misrendered in the words 'was thrust in upon the Persian fleet.'"

Either your critic or Liddell and Scott are guilty of a bad mistake in scholarship (*vide* L.S. sub. ἐκφορέω. 4. Pass, "to be cast on shore": with a reference to this very passage Herod. VIII. 12; *cf.* also ἐκφέρω in the same dictionary). If I sin, I sin in very good company.

(4) In reference to B.C. 479, your critic asks, "Why should they (the Persians) stop at Cithæron?"

I would ask in reply, (1) Why did not the Persians stop in Attica? (2) Why, above all, did the Greeks follow them into Bœotia?

(5) Your critic says, "It is absurd exaggeration to call Taurus 'an all but blank impassable wall.'"

In the part of that chain which separates Asia Minor from the Euphrates region between the pass from Laranda to Kelenderis and the pass of Kiskisos, a distance of 170 miles, there is only *one* pass, the Cilician Gates. The two first mentioned afford circuitous and difficult routes to the Euphrates region. The Cilician Gates are by no means an easy pass. (For Map *vide* Ramsay, "Asia Minor," p. 330.)

(6) Your critic says that "for downright geographical nonsense" it would be hard to beat the description of Pteria as the chief strategic point in the Halys region, as commanding the middle portion of the valley through which the river flows.

He is apparently under the impression that in order to command a valley strategically, a town must be in it. On the importance of the position of Pteria the evidence of Herodotus is sufficiently striking (H. I. 76), "Now Pteria is the strongest position in the whole of this country."

(7) Your critic asks, "Are the Phrygians and the Bithynians still to be called Thracians in the days of Darius?"

His answer is obviously No! Another authority, Herodotus, however, speaking of the races which Crœsus ruled, mentions (I. 28) Θρήικες οἱ Θυνοί τε καὶ Βιθυνοί.

(8) Your critic says, "On p. 378 a whole paragraph is based on a childish mistranslation of Herodotus."

This charge is based on a somewhat careless mistake of his own. I speak of a "decision." He refers to the "discussion" of chapter lxxiv. of Herod. VIII.

I have dealt with all the major charges brought against me. I cannot expect you to allow me space to deal with the minor charges, though I believe them to contain inaccuracies.

G. B. GRUNDY.

THE EDUCATION BILL.

THE Education Bill introduced by the Government on March 24 has been so freely discussed in the public Press that everyone interested in educational work is familiar with its chief provisions. The fundamental idea is the creation of local bodies to supersede School Boards, managers of voluntary schools and technical instruction committees, and to be responsible for the organisation and maintenance of the various educational agencies—both primary and secondary—within their respective areas. The local education authority will be the County Council in counties and the Borough Council in county boroughs; it will work through committees appointed under schemes to be approved by the Board of Education, consisting of members appointed by the County and Borough Councils, with a minority of persons possessing expert knowledge of educational work. The committees will thus be similar to those under which the work of technical education has been carried on since 1889.

In the contributions by Dr. Oliver Lodge, Sir Joshua Fitch and Prof. Wertheimer, which are subjoined, several aspects of the measure are described. It will be evident from these articles, and from the views which have been expressed elsewhere by persons and organisations whose opinions merit attention, that the principle of local educational authorities meets with general approval. But it is apparently impossible for primary education to be considered in England without raising religious difficulties; and the controversy over this subject is of such an uncompromising nature that it threatens to delay or wreck the present measure as it has others.

The abandonment of the Bill would, in our opinion, be a disaster to education in England, for the measure represents an earnest attempt to put our educational system on a sound organic basis. The only way to avoid such a disappointment seems to be to divide the Bill into two parts—one concerned with secondary and the other with primary education—and let each part be dealt with as a separate measure. Secondary education includes technical education, and national progress depends more upon the coordination and extension of these higher stages than upon elementary instruction. What the country needs are masters and managers educated in the truest sense of the term, men with scientific training and sympathies, able to appreciate latent possibilities of industrial developments and anxious to encourage all work which aims at the advancement of knowledge. It is in students of this class that England is lamentably deficient as compared with Germany and the United States, and it is to such students that the country must look for material progress.

We ought not to have to wait for a settlement of the differences of theological parties before organising the agencies for higher education, which have fortunately been emancipated from these difficulties. The Bill as a whole is a comprehensive measure which could be made an Act of decided value to education, but as there seems little hope of removing the opposition to the part dealing with primary education, the sections dealing with secondary education, which are less contentious and are generally accepted, should be separated from it and passed first. The local authorities which would thus be created would then be able to gain experience, and perhaps in the course of time public opinion would be intolerant of the interference of sectarian parties with schemes for secular education. To permit such differences of opinion to delay the establishment of higher education on a sound basis would be a national misfortune.

EDITOR.

I.

The opposition threatened to the Education Bill just introduced by Mr. Balfour may or may not be weighty, but it is voluminous enough to demand some activity and energy on the part of those who realise the immense leeway in secondary education that has to be made up, and who welcome any real and public-spirited attempt to grapple with the difficulties of its effective organisation.

It is unlikely that the new Bill is free from faults, but it clearly represents a strenuous and conscientious effort to legislate in the right direction; to many it appears a statesmanlike attempt to grapple with the numerous difficulties and at the same time to leave as much opportunity as possible open for local experiment, for growing experience, and for the subsidence of needless hostilities; and in any case it should be welcomed by all who are interested in educational progress. For though they may not be able to approve every minute detail, yet the more they study it, the more they will realise the care and forethought which have been exercised in steering through the maze of conflicting interests and in endeavouring to lay down the wisest course.

The form of educational government which has most promoted rapid development and has shown itself to be extremely well qualified to adapt itself to new requirements is the kind of government which controls University colleges. The success and growth of these institutions has been the prominent educational feature of the last quarter century, and they are governed by a council consisting of local business and professional men, not specifically qualified—qualified highly in other directions,—who have sufficient public spirit to give some time and trouble to the work; this body, the council, is advised and assisted in all academic matters by the professorial staff in subordinate conclave, who form a body called the senate, which has no financial power, but has usually in practice, by reason of its special interest and knowledge, a very considerable guiding influence. The business man, when properly advised on technical matters, but only when so advised, is extremely expert as an organiser and conductor of affairs on common-sense lines; he is usually far more efficient in these respects than the academic officers themselves; and the combination of the two works admirably.

The system which has proved so effective may well be extended so as to take control of the schools also. Something like it is what the Government propose. The real education authority is to be the County or Borough Council, an assemblage elected for general purposes, and containing, it is to be hoped—certainly containing in all places where local self-government has been a credit and an inspiring example—the best and ablest of the citizens. It is vital that the best and most competent men shall consent to serve in this capacity, and everything which increases the interest and the dignity of the proceedings of such bodies is to be welcomed. But though each County and Borough Council is the ultimate authority, with power of purse, subject only to the central Board of Education which may be said to take the place of the Court of Governors of a University college as court of appeal and general supervisor, it is not to be the working administrator. This is to be a committee appointed by the Council, together with other persons who may be nominated by representative institutions, and may include experts in education of all kinds; and this administrative body will roughly correspond with the senate, and will have much power, but it must contrive to act so as to carry with it the conviction and the support of the local education authority itself.

The precise constitution of this committee is left undecided by the Bill—a feature which has excited hostile

comment—and the county authorities are asked each to draft and submit a scheme to the Board of Education, so as to allow as much local initiation as possible. This and many other provisions of the Bill may seem, to persons who come new to the subject, as a needless opening of the door to variety and difficulty; but the more we appreciate the different circumstances obtaining in different localities throughout the country, and the more we discuss the matter with representative men who have been connected with official educational matters in the past, the more does some such course seem desirable.

A series of private conferences was held in the University of Birmingham during November 1901, and was attended by a specially invited number of representative educationists, prominent members and officials of School Boards, managers of voluntary schools, and other men of experience and various views, representing opposite schools of thought; and at these conferences a general idea of the provisions which would be likely to secure practical agreement was arrived at. I propose in this article to summarise them and to indicate how far and in what way the Government Bill satisfies the conditions then laid down as most suitable.

First, there are three general conditions which any effective Bill should satisfy, and on which there was universal agreement:—

(A) That all education shall be included in the purview of the education authority so as to secure continuity of the educational system throughout the country.

(B) That the new authority should be sufficiently strong and independent of sectional interests to deal effectively and impartially with educational defects in its district, whoever is responsible for them.

(C) That it should be provided with prompt and efficient means of obtaining funds, both imperial and local, for carrying out its policy; that it should have proper borrowing powers; and likewise the power of compulsory purchase of sites.

To these may be added a fourth, which, though it touches upon controversial topics and when pressed into detail could easily excite difference of opinion, yet in its general form will probably be accepted by all fair-minded men:—

(D) That while insisting on a minimum of efficiency and on representation on the boards of management of all schools drawing assistance from national or local funds, the new authority should recognise the value of the voluntary schools to the nation, and do nothing to discourage the interest of religious bodies in the education of the people.

Next it seems to be quite widely and generally accepted that a unification of educational organisation is desirable, so as to break down the strict line of demarcation between primary and secondary, to raise the status of the primary teacher, and to open a career and the highest educational posts to competent men who enter the profession even at the lowest grade. It is also generally accepted that this general education authority should not be central, but be local; so as to spread the interest, to adapt itself to varying conditions, and to secure the many advantages of distributed local self-government. This was expressed in the first resolution:—

(1) That there should be one local Education Authority, which should control all the educational agencies receiving public support in the district—primary, secondary and technical—and should get into effective contact with institutions for higher education, such as non-local or endowed schools, University colleges and Universities.

But the difficulties begin as soon as it is attempted to lay down a constitution for the new authority. There are many who advocate that one uniform constitution should be laid down in the Act. Others hold that it would be better to let each locality consider what is best for itself, and to have at least the option of formulating a scheme, to be approved and sanctioned by the central authority or Board of Education; but that no scheme should be drafted by that body except in cases where the locality did not choose to exert its power of choice. Although there would be a certain disadvantage in having different schemes simultaneously in force in different places, yet it is likely that each County Council would take more interest in and would take more pains to work a scheme that they themselves had had a hand in drawing up, rather than one which had been forced upon them, in which they had no voice, and might feel that they had no responsibility for its success or failure. Again, it appears difficult to say of any scheme that could be suggested that it is absolutely the best. It may be necessary to ascertain the best by actual experiment, and if different places adopt somewhat different schemes, the best of them may before long emerge and may hereafter be imitated elsewhere. At any rate, the majority of the conference was in favour of some local option in this matter, and adopted the following clauses:—

(2) That each County Council and each County Borough Council, either separately or in combination with other neighbouring councils and with representatives from adjacent boroughs, and in consultation with some recognised educational experts, shall formulate a scheme for the constitution of the Educational Authority in its district, and shall submit it to the Board of Education; subject to the proviso that no scheme is in general likely to be acceptable which does not provide:—

(*a*) That about two-thirds of the suggested Education Authority shall consist of members in some way or other elected by ratepayers of the district (though not necessarily elected for the specific purpose of education).

(*b*) That a reasonable proportion (say in general about one-sixth) of the suggested Education Authority shall consist of members nominated by specified educational institutions of weight and influence in or near the district.

(*c*) That the remainder shall be co-opted according to some scheme to be submitted.

(*d*) That place shall always be found, in one or more of the above classes, for women on each educational authority.

(*e*) That the members of the Educational Authority, whether co-opted or nominated or elected, shall retire in rotation, say one-third every three years or one-half every two years, but shall be eligible for re-election.

Note.—A minority held that it was undesirable to leave even this amount of experiment and variety to local option, but that a uniform constitution should be enforced in the act.

(3) If no scheme is formulated by a County Council, the Board of Education shall formulate one.

(4) Any scheme for the constitution of a local authority, however formulated, shall be published in the locality, and criticisms considered, and petitions heard against it, before confirmation and adoption.

The Government Bill differs from these clauses in the following particulars:—First and most important, it is not the authority itself which is to be thus constituted, but only the working committee; next, the Bill does not dictate to the County or Borough Council in what way it shall formulate a scheme which it shall submit for approval to the Board of Education; and, lastly, there are only two provisos laid down, which, however, embody the essence of the above provisos *a*, *b*, *c*, except that, instead of two-thirds, a majority only is insisted on, and this majority need only be elected by the ratepayers at second-hand, being appointed by, but not necessarily themselves being members of, the council. In practice, however, no doubt a large number of them would be actually elected members of the council. In practice also it is to be hoped that proviso *d* above would always be enforced, for since half the children to be taught are girls, it is only a matter of common sense that place for women should be found on each education authority; and it might have been wise to attract support by definitely inserting this provision. But this and the business arrangements about retiring are left as part of the optional scheme to be drawn up by the various localities; indeed, the whole proposals of the

Government tend in the direction of leaving as much liberty and elasticity as possible, having faith in the county authorities to devise a suitable scheme without coercion from Parliament. This feature, it seems to me, should be welcomed except by persons who have no faith in popular government.

But there is one important item in the Government Bill which was not adopted by the above-mentioned conference, and which appears certain to excite the hostility, and which evidently has excited the hostility, of members of School Boards, though the reasons why they object to it do not lie on the surface. This is a matter on which much controversy turns, and it may be as well to explain it.

In the above proposals of the conference it was all along assumed that the committee appointed to work the educational scheme would be itself the education authority, and the following additional clauses with regard to its financial powers were drawn up :—

(5) That the Education Authority as constituted be an authority subject only to the Board of Education, that it have independent rating power, borrowing power and purchasing power, and be not regarded as a committee of the County Councils with proceedings subject to revision by those bodies.

Note.—Whatever objection may be felt to this independence of rating power for educational purposes, it is felt that if it were not granted the incipient harmony and agreement would be destroyed, for the School Boards would not willingly consent to resign an important portion of their powers to any but a strong and autonomous education authority.

(6) That the local authority shall administer and apportion all public educational funds ; of which it is desirable that a larger proportion than at present should be derived from imperial revenue (since the local rate falls with undue severity on the poorer districts, and for other reasons), and that no limit be placed by Act of Parliament on the rating power for education of a local authority.

But here the Government Bill differs entirely; it constitutes the County Council itself the local authority and gives it full control of the purse (subject, however, to certain limits of rating power, which limits are too absurdly narrow as specified in the Bill, though a means of widening them is provided, for any education higher than primary) ; and the working education body is only a committee of this local authority, consisting of appointed, co-opted, and nominated members. The object of this contrivance is manifest, viz. to leave the ultimate financial control entirely in the hands of persons directly elected by the ratepayers, and to get rid of the anomaly of two independent rating powers. But there at once we touch upon the jealousy or rivalry which has existed between the County Councils and the School Boards, for the latter are not likely to be willing to give up their powers to a body elected for other purposes than education, the members of which are not necessarily even members of the education committee ; nor are they likely to willingly resign their financial autonomy in favour of a mere committee without rating power. This has always been recognised as one of the most difficult points about the Bill, and it is not likely that any solution would meet all objections. On the whole, the Government solution seems to me ingenious and hopeful, but they must be prepared to face a genuine conflict of opinion on this point. Fortunately, the urgency of the conflict is mitigated by the optional provision which permits efficient School Boards to continue for a time ; but the option does not rest with the School Board—it rests with the County Council ; and this fact, though probably unavoidable, may lead to conflict. On the whole, it appears not unlikely that this provision for choice between adoption and non-adoption of the elementary education portion of the Bill may be abrogated ; but strong arguments in favour of it are given below (see paragraphs following 14).

The next four propositions are little more than business arrangements, though it may be convenient to quote them. They are as follows :—

(7) That financial support be not granted to any institution until proper means be taken to secure its effective expenditure.

(8) That any existing powers whereby a locality aids an educational institution nominally outside its area shall be preserved.

(9) That it shall be the duty of each local authority to forthwith examine into the educational need of the district, to report to the Board of Education both on its present supply and from time to time on the further additional supply necessary, and, subject to control and approval by the Board of Education, to take steps for its provision.

(10) A right of appeal to the Board of Education on behalf of any aggrieved institution shall be conceded.

Of these it is satisfactory to find that No. 8 is included in the Bill, so that, for instance, a University college which manifestly serves an educational area without being actually located in that area, can as heretofore be assisted by the council controlling the area.

It is to be feared that No. 10 does not find a counterpart in the Bill. Right of appeal to the Board of Education as an arbiter is given in connection with primary education, but it is needed on behalf of any institution, though not of any individual, which feels itself aggrieved by some action of the local Education Authority.

Then there arises the question as to the proper size of an educational area. It would be desirable, if possible, that each complete area should contain an example of every grade of educational institution, from the primary school to the college and University. This is not feasible, but what is feasible is that for certain purposes some common action could be taken, or some amalgamation effected, by areas which are educationally too small. Moreover, there are many instances where the administrative county area will turn out very artificial for educational purposes, giving rise to much needless overlapping ; and, although it would seem impracticable to mark out new areas, yet even that might be permitted if locally desired ; anyway it would be quite feasible for county authorities to combine for educational purposes, and accordingly the conference adopted the following resolution :—

(11) That local Education Authorities of adjacent districts which for any reason have educational interests in common be empowered to combine, to discuss, and to appoint joint committees for all such purposes as may be common to their areas ; and likewise, if they choose, to combine altogether or amalgamate for educational purposes, so as to constitute a large educational area administered by one authority ; and that facilities for such combination be afforded.

Note.—Opinion was divided as to whether it was feasible to enforce combination among administrative counties for educational purposes, with the object of securing a large dignified and comprehensive educational area.

The essence of this desideratum is provided for in the Act in an ingenious manner, the arrangement of an education committee not itself a County Council facilitating the matter, because plainly county authorities could combine to work their districts by a single education committee nominated conjointly.

The educational standing of non-county Boroughs and urban districts has been a matter which has always given great trouble and excited considerable controversy.

A non-county borough with a large population, for which it has made considerable educational provision, and possessing a penny rating power for technical instruction, would resent being treated by a County Council on the same lines as the surrounding rural districts ; and yet it seemed difficult to constitute so small a body with no great variety of schools in its area an actual Education

Authority. Accordingly the conference adopted the following resolutions :—

(12) That it be exceptionally permitted to some boroughs and urban districts in the neighbourhood of county boroughs to link themselves for educational purposes with the said county borough by mutual agreement instead of directly with their proper county.

(12*a*, supplementary to 12) Any Borough or District Council with general rating power shall be empowered to levy an additional rate for education in its own boundaries over and above that demanded by county authority from the entire area of which it forms a part; but this rate shall not be expended by the Borough or District Council until its recommendations have been submitted to, and approved by, the Education Authority in whose area it is situated.

The Government Bill solves the difficulty in a somewhat analogous but still more liberal manner —some think an over-liberal and unwise manner;—the Borough Council itself, when it represents more than a certain population, is constituted the local Education Authority, but it is given the option, not only of sharing, but actually of transferring, the responsibility, either the whole or a part, to a County Council, provided the latter is willing to take it, and at the same time its independent rating power for education higher than elementary is preserved.

It is to be hoped that the power of amalgamation between neighbouring counties, boroughs, and urban districts will be exercised; for this question of the size of an administrative area is really a very important one. Many eminent persons hold that an area the size of a Province would be in many ways better and more dignified than the present area of an administrative county: a return, as it has been called, to the heptarchy, the natural provinces of which were marked out by physical features, and have always retained a certain set of common interests. These ancient provinces are large enough to support highly dignified governing bodies, to which a great part of the local government still at present cumbersomely and expensively administered at Westminster could with propriety be transferred, thereby setting free the time of Parliament for Imperial purposes, and leaving local questions connected with locomotion, drainage and the like to be dealt with by the localities which most thoroughly understand them. It is just possible that amalgamation for educational purposes might form the beginning of this much-to-be-desired result.

Returning now to the business arrangements which must be made by an education committee, it is manifestly desirable that the authority for a large area shall not attempt actually to manage the schools in its area, but shall operate on them through Managers more immediately in contact with each school, such a board of managers being in most places already in existence, and being therefore conveniently continued, though with some modification.

The following resolutions were adopted by the conference, and similar provisions are included in the Bill:—

(13) That the Education Authority, though having control over all schools dependent on public funds, shall not constitute itself a board of management for any school; but shall provide that managers be appointed or continued for every school or group of schools within its area, according to some scheme approved by the Board of Education.

(15) In order to establish and maintain connection between the managing bodies and the local Education Authority, the latter shall nominate one or more persons to serve on each managing board or governing body concerned with any school or group of schools deriving financial benefit from rates or taxes.

(16) That in order to facilitate connection with and representation from the local authority, existing non-elected managing bodies be combined with one another for purposes of administration, on lines similar to those in use under the Aid Grant Act of 1897.

But it is desirable that those specially appointed managers who represent the controlling body shall report to that body regularly. Otherwise the control might gradually cease to be effective.

I have omitted No. 14, which had to do with the future of the more efficient School Boards—those which had done good work and had gained the confidence of the community, and which it seemed undesirable to suppress. It was a very difficult point, and no satisfactory solution was arrived at. The resolution may be quoted, in order to emphasise the difficulty; and it was drawn in vague terms in order to cover, not only School Boards, but the boards of all other schools which are to be affected by the Act.

(14) That existing administrative educational bodies, wherever they have shown themselves efficient, be continued in their office and function as managing boards, and in such dependence on popular vote as already exists, and with their present attendance authority, but without rating power, and subject to the control, as hereafter defined, of the local Education Authority.

What the Bill proposes, however, is not this poor compromise; it proposes to leave it optional with each locality, at any rate for a time, to decide whether the existing School Board shall continue to take control as heretofore of primary education, or whether it shall be at once superseded by the new and comprehensive authority. Perpetuating the School Board system in places will have the effect of perpetuating there the undesirable dislocation between primary and secondary education; but, on the other hand, it will avoid introducing sudden disturbances; it will allow the present conditions, wherever efficient, to persist for a time; it will allow business to continue during alterations, and it will pave the way for a gradual change on to the new lines when time and experience are ripe. Hence it appears to me that this optional clause, permitting the transfer of primary control to be locally delayed for a time, is to be distinctly welcomed as affording an easy and elastic means for introducing the provisions of the Bill with the consent of each community, rather than forcing them to accept them prematurely. Ultimately it is to be hoped that but little conflict will arise between School Boards and County Councils on this matter, because no County Council would be foolish enough to overlook the advantage of nominating the prominent and efficient members of School Boards on to the new Education Authority, thereby continuing to reap the benefit of their wisdom and experience, just as they will continue the Board officials in practically their present office and function.

Those who advocate the abrogation of this optional clause, and the compulsory forcing on each County Council of full and immediate responsibility for primary as well as for secondary education, would do well to remember that voluntaryism is the essence of local government in England; and that if a body is overweighted, or prematurely loaded, people of judgment may decline to serve on it. Compulsory adoption of the Act would logically involve a measure to enforce service on a County Council.

The vexed question of how to improve and give rate aid to the schools provided by religious denominations, and of what special privileges can be conferred on such schools in return for certain pecuniary sacrifices made by the denominations interested in them, has excited, and will no doubt continue to excite, much controversy; but, as it seems to me, controversy of a belated kind, more noisy than effective, and largely maintained by those who have lived through the sectarian controversies of 1870. To the younger men these sectarian difficulties loom very small;

it is felt to be fair that if a religious denomination provide and keep a school in effective order, it should have the power of giving its specific instruction during certain limited hours, arranged so that scholars not belonging to that denomination may be withdrawn at the wish of their parents; and it is felt to be unfair that the secular instruction of the children in the district which such a school serves should suffer by reason of deficient funds owing to sectarian jealousies; it is felt, in fact, that the district can be properly called upon to support such a school in as thorough a manner as any other, provided always that the ratepayers' authority be extended (*a*) to a voice on the managing board in accordance with the above resolution No. 15, and (*b*) so that it shall have an effective voice in the appointment and dismissal of teachers. Accordingly the following resolution, together with the "powers and functions" numbered 3, 4, 5, 6, 7, below, was adopted, and practically represents what is, or may be under a "scheme," provided by the Bill; except that very unfortunately the word "dismissal" has escaped explicit mention. It may be held to be legally included in the word "appointment," but it is a vital matter to get security of tenure for all teachers, and not leave any of them at the mercy of individual action unchecked by the Education Authority.

(17) That a school whose buildings are the property of a religious organisation, by whom they are maintained to the satisfaction of the local Education Authority, shall be regarded as a privileged school in which special religious instruction is permitted at certain hours, in accordance with a time-table to be submitted by the managers to the Education Authority for its approval, and subject to the conscience clause of the Act of 1870.

Note.—A small minority considered that the upholders of these privileged schools, managed by non-elected bodies, though under the control of an elected educational authority, should be called upon to provide one-sixth of the income in addition.

It is desirable, however, and it may be feasible, to introduce a clause giving to other denominations, which are not providing a school, if they are in sufficient numbers and if there is no other school in the neighbourhood, to make application, not only for mere withdrawal of their children from the specifically denominational religious instruction provided, but, in addition, for the supply of general Biblical teaching for those children to attend in the same school at some other hour.

This question of the so-called voluntary schools—which is a misnomer, the proper title being denominational schools or privileged schools—is by no means an insignificant one, since more than two-thirds of the schools in the country are of this kind; and if they were not taken advantage of, it would not only be a blow to educational and humanitarian enthusiasm, but it would involve the ratepayers in enormous additional expense. At present these schools are suffering from extreme poverty, the voluntary contributions and the Imperial grant together being quite inadequate for their proper maintenance; and the buildings themselves are often inadequate, antiquated and unwholesome. With rate aid and proper control of teaching appointments, no longer leaving teachers subject to the caprice of an accidentally injudicious local clergyman, educational efficiency can be secured; and the denominational subscriptions will still be required, in some places even more than hitherto, in order to put the fabric into a satisfactory condition and to maintain it in substantial repair, as required by the Education Authority. If they do this, the denominations cannot be expected to do more, and they are entitled to give specific religious instruction at certain hours on the strength of this. But if they go further than this in their demands for rate aid, if they resent any element of popular control—resent, for instance, any interference with their appointment and dismissal of teachers, or any influx of nominated members on to their managing board, that is to say, if they resent effective control of their rate-aided secular instruction—they will be taking an unwise course, and must not be surprised if the clauses in the Bill, which already give them everything to which they are reasonably entitled, are opposed so strongly as to be modified in a direction opposite to that which they desire. It is undoubtedly the interest of Churchmen, meaning by interest, not selfish interest, but public and denominational interest, to support the Bill; but the unwisdom of some few of the letters which have appeared in its support is extreme.

The last resolution adopted by the conference, having reference to the training of teachers, unfortunately has no corresponding clause in the Bill. It ran as follows:—

(18) That Education Authorities shall be empowered to enter into relations with Universities and University colleges and other institutions for higher education, in order to make provision for the proper training of teachers; and that after a certain date special sanction should have to be obtained for the employment of unregistered teachers.

But it is to be hoped that the omission has no real significance, that operations for the training of teachers will be in every way encouraged, and that it was only omitted because of the inadvisability of loading the Bill, or the duties of the new Education Authorities, with more than was absolutely necessary.

This represents all that I need now say on the general subject. The remainder of what the conference did was to draw up a specification of the "powers and functions" of the committee, stating in what way it should exercise control over the schools in its area, and what was meant by "control." It may possibly be useful to County Councils and other bodies engaged in formulating a scheme if these be here quoted; but it may be remarked that the first two are perhaps somewhat doubtfully wise in their present too unrestricted form.

Specification of powers and functions.

The functions and powers of the local authority shall be:—

(1) To keep a register of the efficient schools in the area, and to transfer schools and endowments from places where they are not wanted to places where they are.

(2) To make orders for the use of endowments or other grants, for establishing scholarships from schools to other schools or to colleges and Universities. and

(3) To inspect all schools in its area as to buildings sanitation, and publicly aided schools as to educational efficiency, and to make regulations in accordance with the reports of its inspectors.

(4) To withhold financial aid from any school and to close any publicly aided school which fails to comply with its regulations or which is educationally inefficient.

(5) To frame a scheme to be submitted for approval to the Board of Education for the remodelling, when necessary, of the constitutions of existing publicly aided schools, and for providing new schools.

(6) To receive and consider the curriculum of each publicly aided school, as submitted by the board of managers; to amend and refer back any part of such scheme; and ultimately to approve the curriculum adopted, having regard to the educational needs of the district.

(7) To receive and consider recommendations of the managing board concerning the appointment and dismissal of teachers in the schools under its management, and to be the final court appeal in such matters.

(8) "Control" shall mean the exercise of any of these powers.

Oliver Lodge.

II.

The Bill recently introduced by Mr. Balfour is a complex measure, carrying with it some consequences which are not apparent at first sight. Many of its clauses—notably that which makes the adoption of

some of its provisions voluntary on the part of the County Councils—will doubtless be subject to much criticism and to many amendments in detail before it passes into law. Meanwhile it may be useful to review the chief features of the Bill, as they affect (1) technical, secondary and higher education, and (2) the public elementary schools.

Part II. of the Bill follows in the main the line indicated in the former Bill of 1896, which was withdrawn by the Government of that year. It gives to each council of a county and of a county borough, and to the council of any other borough with a population of more than ten thousand, the name of the "local education authority," and empowers it to supply or aid the supply of education other than elementary. The Technical Instruction Acts of 1889 and 1891 are repealed, and with them disappears the definition of "technical instruction," which has practically restricted the application of funds under those Acts and under the Local Taxation (Customs and Excise) Act to technical and scientific instruction. The local education authority of the future is therefore set free to allot its revenues to advanced instruction in any form which the circumstances of the district need, whether scientific, commercial, literary, technical or manual, or whether, as is more probable, the secondary schools include in their programmes all of these forms of instruction in varying proportions. This is a clear gain; the Bill may, it is to be hoped, encourage the formation of a sounder public opinion respecting the true scope and purpose of a liberal education, as distinguished from the specific preparation of the student for any one form of practical or industrial pursuit. Since in another part of the Bill (clause 18) evening scholars and scholars above the age of fifteen are excluded from the elementary schools, and presumably from a share in the ordinary Parliamentary grant, it may be inferred that, in addition to the existing grammar and endowed schools, and technical and secondary schools generally, all the higher-grade and continuation schools, and evening schools now controlled by the School Boards, will come into the domain of "higher education" and will receive aid only under the provisions of Part II. of the new Bill. Beside these, it is to be assumed that the local education authority will have under its care the training colleges for teachers, the pupil-teachers' central classes, and the management of local scholarships and of such endowment funds as are applicable to education in their respective districts.

The resources available for advanced education under all these forms will be drawn from the fees of the scholars, from the whole residue of the fund generally known as "whisky money" and provided by the Local Taxation Act, and from a rate which is not to exceed twopence in the pound in counties and county boroughs, or a penny in the pound in non-county boroughs. It is manifest that these resources will not suffice to fulfil all the purposes just enumerated, and will leave little chance for the establishment of such new schools or colleges as may be needed, or for any adequate organisation of secondary instruction in the whole country on a generous scale. Moreover, it is to be observed that the new educational authorities will be only "committees" of the County Councils. They will have no power to raise rates or to give effect to their own recommendations, but will act in all respects in subjection to the veto of larger bodies, which are chiefly concerned with county business, with the water supply and with gas, tramways and sewage, and will be strongly tempted to keep down the rates and to give to the interests of education a subordinate place. It may fairly be concluded that the measure of the Government, if passed in its present form, will have the effect of repressing rather than encouraging educational enterprise, the expansion of existing institutions, the establishment of new ones, or the trial of new experiments.

This serious defect in the constitution of the local educational authority becomes more evident when we consider its probable influence on elementary education. At present the School Boards, which are the popularly elected administrators of the public funds available for elementary education in a given district, are under no restriction as to the local contributions to be levied in the form of rates, and are responsible only to two superior authorities—the ratepayers who elect them and the central Board of Education at Whitehall. Under the proposed measure, the managers of schools will be placed in relation to three authorities—the Board of Education, the County Council and the nominated Committee. It is difficult to see what can be gained in administrative efficiency or in unity of educational purpose by this arrangement. The measure will certainly check the ambition of "educationists" who are busy in discovering new methods and increasing the usefulness of the schools, and in effect it will encourage local authorities to prefer economy to educational improvement. As to the Board of Education—hitherto known as the Education Department—its policy of late has been to abdicate many of the most important functions which it once discharged to the great advantage of the public. Until lately it set up standards of excellence, and sought by graduating its grants to secure that these standards were attained. It has in recent years deemed it better to relieve itself of all attempt to discriminate between good, bad and indifferent schools, and has declined to examine the scholars and has awarded practically the same grant to all schools alike. It now proposes to leave to school managers the responsibility of framing such schemes of instruction as will satisfy the local public, and of seeing that these schemes are carried into effect. Thus between a central Department which is ceasing to exercise more than nominal control and a County Council which may chance to consist of persons hostile or at least indifferent to the intellectual progress of the people, or are else absorbed in county business of another kind, our principal safeguards for such progress, which have hitherto been found in School Boards elected *ad hoc*, and presumably caring most of all about the credit of their own town and the goodness of their schools, will be seriously weakened. It is impossible to look forward without grave misgivings to the future of popular elementary education in England under the new conditions contemplated in the Bill.

But, after all, the true significance and the obvious *motif* of the measure are to be sought elsewhere. Its best friends do not claim that elementary education under the new conditions will become sounder, larger in its scope, more scientific in its methods, or nobler and loftier in its aims. They advocate it chiefly because it will bring relief to the supporters of voluntary schools, especially to those of the Established Church. It is well to recall the actual facts of the present situation. About half of the children under instruction in England and Wales are taught in Church schools, owing to the fact that in the rural districts there is generally but one school in the parish and that the parents have no opportunity for exercising a choice. In towns, however, where such an opportunity exists, the Board Schools are generally fuller and more popular. Out of a total expenditure of nearly thirteen millions of pounds upon elementary education, the Church of England contributed last year about six hundred thousand pounds, in the form of subscriptions, congregational collections, and grants from local endowed charities. For this sum the representatives of the Established Church secured the sole management of schools attended by more than two millions of scholars, and the full power to give distinctive theological teaching and to administer the schools in the interests of the Church. To a plain man this arrangement appears to be an excellent bargain, from the point of view of those who regard those interests as supremely important. But it is always described in diocesan conferences,

episcopal charges and religious newspapers as a gross injustice and an "intolerable strain" upon the benevolence of Church people. Accordingly, the Government has been urged by the advocates of the denominational principle to make two concessions by way of relief: (1) to increase the public grant so as to make all voluntary subscriptions unnecessary, and yet to leave the existing managers free to preserve the distinctive denominational character of their schools, and (2) to repeal that clause (the fourteenth) in the Education Act of 1870 which forbids the teaching of creeds and formularies in the Board Schools, and so to permit the ministers of religion to give separate instruction in those schools to the children of their respective flocks. Both of these proposals were accepted by the Government and embodied in the abortive proposal of 1896. The second, however, does not appear in the new Bill. The Cowper Temple clause is not repealed, but will still remain applicable, not only to all existing Board Schools, but presumably to all new elementary schools to be provided by the proposed education authority. But to the former of the two demands, the Bill makes a liberal response. Denominational schools are to be financed and supported in future at the expense of the rates, on the easy condition that the managers provide and maintain in repair the school building—not, it should be observed, the furniture and equipment—and shall continue to maintain it as a Church school, subject only to the proviso that a number of members of their body, not exceeding one-third, shall be nominated by the local authority.

It will be seen from a careful study of the Bill that its dominant purpose, so far as regards elementary education, is to encourage the multiplication of denominational schools, to remove the "intolerable strain" of maintaining them from the shoulders of the churches to those of the ratepayers, to strengthen the denominational system and to give it a renewed chance of permanence. It may be that this great change in the national policy will commend itself to the approval of the English Parliament and people, but its meaning should not be misunderstood. It was the prayer of the Greek soldier, "Let me die in the light," and if, after all our experience and the efforts of statesmen to make our system of public instruction more national and less sectarian, we are really destined to see that system impaired if not destroyed, we ought at least to have our eyes open, and to see clearly what is the nature of the present reactionary movement and whither it tends.

J. G. FITCH.

III.

The two main causes for the relative poorness of British technical education as compared with that given in Germany and the United States are, (*a*) the fact that comparatively few British manufacturers have as yet learned the need for the efficient technical training of those whom they employ, and (*b*) the chaotic condition of the secondary, and part of the elementary, education of this country.

The Government Bill is a step towards the rectification of the latter defect, for not only does it make possible some organisation and improvement of secondary education, but it also tends to secure greater efficiency for the denominational elementary schools, many of which are at present in a starved condition.

Most of those connected with technical education will be glad to see that the Government has chosen as its educational authority a body on which, while the representative element will rightly predominate, there will be a minority of educational experts. Evening classes will come under the control of this new authority, and it will be possible to grade them properly and to secure that the bulk of the money spent upon them is not frittered away in simply giving many thousands a mere smattering of knowledge. At present this is the case to a considerable extent, and one reason for it is the lack of proper coordination between evening classes in Board Schools and higher institutions; such coordination would encourage a much greater number of the Board-School pupils to continue their studies to a stage when these studies might prove of real benefit, not only to the pupils, but also to the nation.

The Bill has two serious defects, both of which, however, can be easily remedied. In the first place there is the optional clause, which leaves it to the various county and borough councils to decide whether or not they will make themselves responsible for the whole of the education in their districts. If this stands it is certain to perpetuate old difficulties and to give rise to a whole series of new ones; it is to be hoped, therefore, that the Government will stiffen its back and leave no option in regard to this important matter.

Secondly, there is no clause in the Bill which appears to safeguard the interests of technical education by ensuring that the residue under the Local Taxation (Customs and Excise) Act, 1890, shall continue, as heretofore, to be devoted to the purposes of technical education. It is of great importance that this should be specifically enacted, as otherwise there will be a danger that, in view of the increased demands upon the ratepayers for improved elementary and secondary education, the local authorities may curtail the sums they now expend on technical education, though those sums are still inadequate when compared with the sums spent by our leading industrial competitors.

Finally, it would be well to include in the Bill some provision, not only for the coordination of work within the district of each local authority, but also for the coordination by means of the central educational authority of the work undertaken by the local authorities themselves. This is particularly necessary in the matter of technical education, for, if we are to have technical colleges which will be comparable in efficiency with those of the United States of America, we must gather large numbers of students into a relatively limited number of centres, and provide in each centre the best possible equipment and a teaching staff on a scale much more generous than in any example at present to be found in Great Britain. Elementary technical education ought, of course, to be given as far as possible in all parts of the country, but the attempt of small towns to give the highest technical education to few students should be discouraged. These students should be drafted into centres, and the determination as to where these centres should be placed should be left in the hands of the central educational authority. Moreover, higher technical education being a matter of more than local importance should be subsidised, not only, or mainly, by local authorities, but very largely by the State itself. One may hope for such increased State aid at present, but it seems scarcely justifiable to expect it; our statesmen have yet to learn that expenditure on an army and a navy to keep the "open door" for our commerce will not suffice to enable us to meet foreign competition, unless we expend time and money on the training of our industrial and commercial leaders in the same liberal and enlightened manner as is the case in the foremost foreign countries.

J. WERTHEIMER.

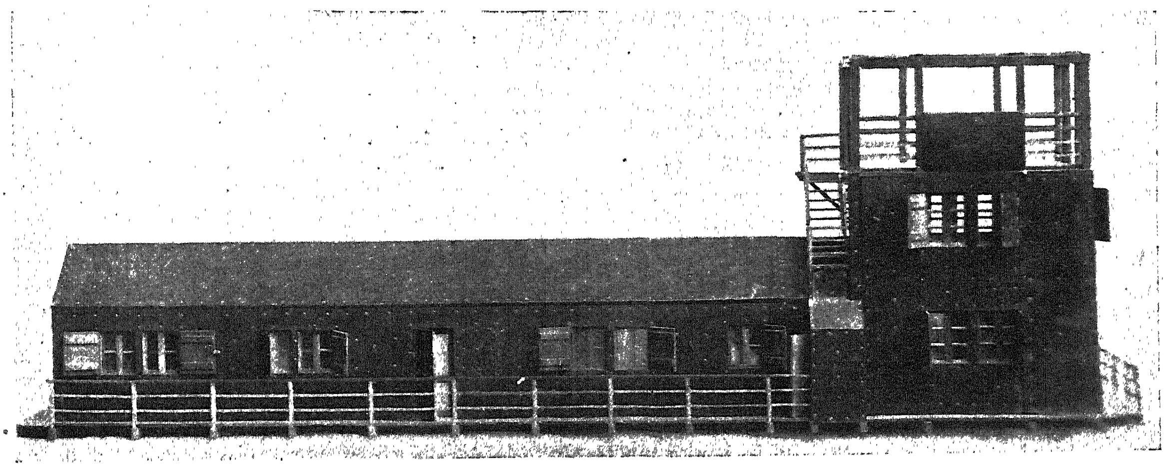
THE REGINA MARGHERITA OBSERVATORY.

THE investigation of the physiological phenomena which present themselves when man ascends to high altitudes is as fascinating as the results are, or promise to be, important. The fascination and the importance are connected with the complexity of the problems which have to be dealt with. The effect on respiration due to the diminished oxygen of the rarefied

air, so far from being the one thing to be studied, as the casual observer might suppose, is perhaps not even the chief thing. Of still greater importance, probably, are the manifold effects of diminished pressure on all the tissues and organs of the body, on the vascular system in all its parts, peripheral and central, and the far-reaching secondary results of the changes in the circulation thus brought about. These are further complicated by the influence of variations in temperature and in the qualities of the sun's rays.

It is through their complexity that the problems in question hold out so much promise; for they carry us beyond the mere question why such or such physiological incidents occur during a high mountain ascent, they lead us more or less directly to fundamental matters of physiology.

To solve these problems two things are needed—the possession of exact instruments of precision, and the opportunity of making use of these instruments at ease and with freedom from disturbance. The observations necessary to solve the problems which we have now before us cannot be satisfactorily conducted by means of rough instruments carried in the pocket, and cannot be adequately made in the open while the observer, blown about by a cutting wind, is steadying himself on his ice-axe. Happily, both these needs can now be supplied to any competent observer whose inquiry justifies the concession of them.



The Regina Margherita Observatory. The first room to the left of the two-storied part of the Observatory is the physiological laboratory.

It was a happy thought of the Dowager Queen Margherita of Italy, whose love for the Alps is known to all the world, to convert into a scientific observatory the Regina Margherita Hut, which stood on the Gnifetti Peak of Monte Rosa at an altitude of 4560 feet, and which had proved of such service to mountain climbers. At her spontaneous suggestion, and by her beneficence, assisted by the Italian Government and with other help, the Hut, largely through the zeal and activity of Prof. Angelo Mosso, of Turin, has been transformed into the Regina Margherita Observatory, fitted up for scientific observations of various kinds.

Prof. Mosso is a physiologist, especially interested in the physiological problems of high altitudes, as shown by his book "Life of Man on the High Alps," and it is through his care that in the Regina Margherita Observatory, in addition to the provision for meteorological, astronomical and other physical observations, physiology has not been neglected. One of the rooms has been set apart for physiological observations and experiments. The great benefit thus rendered to physiology was acknowledged at the International Congress of Physiology held at Turin in September last under the presidency of Prof. Mosso. On the motion of Prof. Bowditch, of Harvard University, it was unanimously resolved to recommend the physiological laboratory forming part of Regina Margherita Observatory to the International Association of Academies as worthy of international support.

Nor was this the only token of approval shown at the Congress. One of the features of the Congress was an exhibition of physiological apparatus gathered from various countries; many of the pieces so shown, including several valuable exhibits from this country, were presented by the makers or private individuals exhibiting them to the Observatory. These, under the care of Prof. Mosso, now belong to the physiological laboratory of the Regina Margherita Observatory.

Hence any physiologist who desires in the ensuing summer vacation to enjoy the united pleasures of high Alpine life and physiological investigation, and we trust that there are not a few such, can do so with ease or even in luxury, finding in the Observatory, not only quiet and shelter, but also almost every apparatus and appliance which he is likely to need. I think I may venture to say that my friend Prof. Mosso deserves the warm thanks, not only of all physiologists, but of all men of science, for what he has thus done. M. FOSTER.

PROF. EXNER ON SCIENCE AND THE STATE.

THE Vienna correspondent of the *Times*, writing on the 7th inst., comments upon a recent address of Prof. Exner which deals with the coming rule of technically trained men, that is, of men who can apply the principles of natural science; engineers trained in colleges as well as in works. The encouragement to scientific education given by foreign statesmen excites in this country only a feeble attention not unmixed with contempt. With us, higher education is still what it was in the time of Queen Elizabeth, and its advocates affirm that the education of men like Burleigh and Bacon, of Coke and Raleigh is good enough for statesmen of the twentieth century. This explains our difficulty in understanding Prof. Exner. Much of the pure science of the world is due to such British genius as could escape the academic net, and yet the power to apply that science is carefully kept away from the British people. We have started all the

branches of engineering; we have invented nearly all the important things, but the great development of these things has gone out of the hands of the amateurs of our nation. It is because our statesmen are Gallios who "care for none of these things," because they know nothing of science. Huxley failed to move them. The German Emperor's fosterage of engineering only amuses them, and hence our manufacturers blame everything except their own ignorance for their loss of trade. Prof. Exner wants to put the technically educated man in charge of all departments of Government which have to do with manufacture and distribution; with the use of all tools, including, we presume, guns and other weapons of destruction. He does not seem to know what is so obvious to us in England; that the Ministers in charge of departments must have had such a training of another kind that it is impossible for them also to be engineers. All we ask is that they shall know just a little about science, so that they may be able to take scientific advice. But alas! even this condition of things is remote. However important it would be to have men of the quality of engineers as their advisers or in charge of the various parts of a great department, there are qualifications more important—power to coax the Treasury for necessary money; social qualities such as come from good birth and enable one to keep one's superiors favourably disposed; qualities created by official life which enable one to work obediently as part of the official machine and never get into a rage; the knowledge that if ever there is a conflict between official law and a law of nature, it is the official law which must be obeyed. For our reform what is wanted is a cataclysm, rather destructive, but not too much so.

J. P.

NOTES.

We see with deep regret the announcement of the death of Prof. A. Cornu, whose numerous researches in physics are known throughout the scientific world. An account of the life and work of this distinguished investigator will appear in another issue of Nature.

By the death of Lord Kimberley, the office of Chancellor of the University of London becomes vacant. Of the names of those who have been mentioned as likely to fill it with advantage that of Lord Rayleigh is obviously the most appropriate. The new teaching University of London must achieve a high reputation on scientific lines or it will fail of its mission; a mere politician as a figure-head would be an anachronism.

Prof. Ray Lankester, in a letter to the *Times* of April 15, raises a new point in relation to the Rhodes scholars at Oxford. He states that the University of Oxford keeps its college residences, lecture rooms and laboratories open for only twenty-one weeks out of the fifty-two which make up a year; so that "it will not be worth while for a young German of ability to sacrifice three or four of the best years of his life to dawdle through the Oxford half-time system, even when paid 300*l.* a year for doing so." If it be true that the laboratories are shut for thirty-one weeks in the year, then certainly the sooner William Morris's idea of dispersing the inhabitants and consecrating Oxford to Death and Beauty, the better for others as well as the Germans to whom Prof. Lankester refers.

The high esteem in which the late Sir John Donnelly was held was shown by the large body of mourners that attended his funeral at Brompton Cemetery on Friday last besides the members of the family. The Lord President of the Committee of Council on Education was represented; and among other mourners were the Clerk to the Council, the vice-president and officers of the Board of Education, representatives of the Victoria and Albert Museum, Geological Survey and Museum of Practical Geology, Royal College of Science, and Solar Physics Observatory. The Royal Society, Royal Academy, and the London Technical Education Board were also represented. Among the wreaths was one bearing a card on which was printed: "A tribute of affectionate regard from the vice-president of the committee of council, officers and staff of the (late) Department of Science and Art, including the Victoria and Albert Museum, the Royal Colleges of Science and Art, and the Geological Survey and Museum, 11 April, 1902." Another wreath was from the Dublin Science and Art Institution: "In token of affectionate remembrance and sincere regret from those who served under Sir John Donnelly." Other wreaths were sent by Sir Trevor and Lady Lawrence, Sir Lawrence and Lady Alma-Tadema, and many others. The Victoria and Albert Museum was closed on the morning of the funeral.

Dr. J. Larmor, Sec. R.S., and Dr. Oliver Lodge, F.R.S., have been elected members of the Athenæum Club under the rule which empowers the annual election by the committee of nine persons "of distinguished eminence in science, literature, the arts, or for public services."

At the meeting of the American Philosophical Society held on April 4, the following were elected to membership:—*Residents of the United States*—Dr. J. A. Brashear, Dr. Andrew Carnegie, Prof. W. B. Clark, Prof. Hermann Collitz, Mr. G. K. Gilbert, President A. T. Hadley, Prof. G. E. Hale, Prof. P. Haupt, Prof. A. A. Michelson, Mr. C. Hart Merriam, Prof. T. W. Richards, Prof. F. E. Schelling, Prof. R. H. Thurston, Mr. B. C. Tilghman, Prof. R. S. Woodward. *Foreign Residents*—Prof. A. H. Becquerel, Prof. J. G. Darboux, Sir Michael Foster, K.C.B., F.R.S., Prof. G. Johnstone Stoney, F.R.S., Prof. S. P. Thompson, F.R.S.

As already announced, the German Association of Natural Philosophers and Physicians will hold its seventy-fourth annual congress at Carlsbad on September 21–28. As on former occasions, the rule that lectures and debates may be carried on in any language of the world will be followed, and foreign visitors will be accorded the same privileges as the ordinary members of the association enjoy. It is estimated that between 6000 and 8000 representatives of natural philosophy and medicine will gather at Carlsbad, and great preparations have already been made there to receive the members and friends of this famous association. Nearly all the principal professors of the Berlin, Vienna, Prague and most of the other continental universities and important colleges will be present, and twenty-eight different branches of ancient and modern science will form the programme for the lectures and debates. At the exhibition of scientific objects, which will be held in connection with the congress, no charge will be made to exhibitors for the space required, nor will any entrance fee be asked from visitors. Inquiries or letters should be addressed to "The 74th Congress of Natural Philosophers at Carlsbad."

In reply to a question relating to the North Sea Fisheries, Mr. Gerald Balfour stated in the House of Commons on Monday that the Government has agreed to take part in the international scheme of investigations connected with fishery problems in the North Sea and adjacent waters as proposed by the conferences held at Stockholm and Christiania, and Parliament will be asked to make a grant to defray the cost of the British share of these investigations. These funds will be administered by a departmental committee with the advice o scientific experts. The details of the investigations will no doubt be finally settled at the forthcoming meeting of the inter

national council at Copenhagen, at which Great Britain will be represented, but the date of which has not yet been fixed. The Board of Trade has also appointed a committee under a minute dated August 13, 1901, to inquire and report as to the best means by which the State or local authorities can assist scientific research as applied to problems affecting the fisheries of Great Britain and Ireland, and, in particular, whether the object in view would best be attained by the creation of one central body or department acting for England, Scotland and Ireland, or by means of separate departments or agencies in each of the three countries. Quite apart from this important question of scientific research, the Board of Trade has, with the assistance of another committee, considered how the present system of collecting fishery statistics in England and Wales could be improved and extended. The chief recommendations of this committee are referred to below.

THE *Times* has published the recommendations of the inter-departmental committee appointed "to inquire into the system of collecting fishery statistics in England and Wales, and to report how it could be improved and extended, and what additional cost (if any) would be entailed thereby, having special regard to the opinion expressed by the Select Committee of the House of Commons on Sea Fisheries, 1893, and the proposals of the Stockholm Conference, 1899." Among the suggestions are:—the extension and improvement of the present system of employing collectors at the fishing ports with the view of obtaining fuller details relating to fishery statistics; the preparation of separate returns as to the amount of fish caught in Icelandic and Faroese waters and in the Bay of Biscay and on such other new fishing grounds as it may from time to time be found desirable and practicable to distinguish; and that conger eels, dabs, gurnards, lemon soles, skate and rays, and whiting should be separately distinguished. The present report does not extend to statistics of salmon or fresh-water fish. The adoption of the recommendations would involve an annual expenditure on the collection of fishery statistics of 2135*l*., or 1435*l*. beyond what is provided at the present time, and a further annual expenditure of at least 1000*l*. for the supervision of collectors and for obtaining the additional information already described.

NEWS has come to hand that Dr. Elliot Smith, professor of Anatomy in the Medical School at Cairo, has been given two months' leave of absence to investigate at once some human remains discovered at Girga, in Upper Egypt. The graves containing the remains are said to consist of a continuous series extending over an interval of at least 8000 years, which represent the most archaic of prehistoric periods. The bodies are so well preserved, owing doubtless to the dryness of the atmosphere where they were interred and to the perfection of interment, that not only can the hair, nails and ligaments be made out, but the muscles and nerves. In almost every case the brain is said to be preserved, and the climax has been reached in two examples where the eyes with lens in good condition are present, and in others in which Dr. Elliot Smith has already observed the limb plexures and great splanchnic nerve. There are also now unearthed a series of later prehistoric graves, ranging throughout the first fifteen dynasties, others of the eighteenth, and yet others of the Ptolemaic and early and recent Coptic periods. This vast "cemetery" has been excavated by Dr. Reisner for the University of California, and we can but congratulate him and the Egyptian Government on having secured the services of so competent an anthropotomist as Dr. Elliot Smith, whose full report will be eagerly awaited.

A MEMORIAL to the late Dr. John Anderson, F.R.S., the first superintendent of the Indian Museum at Calcutta, has recently been erected in the upper eastern verandah of the main Chowringhi building. The memorial is in the form of a full-face medallion portrait in bronze, and is the work of the eminent Scottish academician, D. W. Stevenson. It is completed by a brass tablet, upon which the following words are inscribed:—"John Anderson, M.D., F.R.S., First Superintendent of the Indian Museum, 1865–1886. Besides organising and arranging the zoological and archæological sections of this Museum, he made large collections and many discoveries in Yunnan and Mergui, and achieved enduring distinction by his original contributions to vertebrate zoology. (Presented to the Museum by his widow and friends, 1901.)" Referring to the memorial, the *Englishman* remarks:—"As the gift of Dr. Anderson's friends, the location of the memorial is happily chosen; but from a wider point of view the museum itself—at least in its zoological and archæological sections—is *monumentum aere perennius* of Dr. Anderson's work in India, for although the institution has considerably developed since his time, it has done so strictly along the lines—well in advance of their day—that he laid down and fashioned. Dr. Anderson will also be remembered as one of the earliest advocates of a zoological garden for Calcutta, and as having greatly helped to shape the institution also when it was started." Every naturalist will be glad to know that Dr. Anderson's valuable work has been commemorated in this way. His labours could not easily be forgotten even if no memorial had been erected, but students unfamiliar with his career should be reminded of the great work he accomplished. In connection with this subject it is worth mention that the volume on "The Mammals of Egypt," on which Dr. Anderson was busily engaged when a brief illness unexpectedly terminated his useful life, will be published during the present year. This will be the second volume of Dr. Anderson's important work on the zoology of Egypt, and it will be similar in every respect to the first volume, on the reptiles of Egypt.

IN a discussion on West Africa at the monthly dinner of the London Chamber of Commerce on April 9, Sir Harry Johnston remarked that we were much behind Germany and France in respect of the scientific examination of the territories under our control. Writing to the *Times* upon the subject, he defends the Foreign and Colonial Offices from charges of want of sympathy with purely scientific work (examination of rainfall, fauna, flora, geology, minerals, &c.) in our African possessions by pointing out that they were often prevented from carrying out such work by the reluctance of the Treasury to expend national moneys in that direction. Referring to the Uganda Railway he says, "if in past decades we had been allowed to spend, say, 20,000*l*. in the scientific examination of East Africa, the knowledge thus acquired might have enabled us from omniscience to make the Uganda Railway for some half a million less money. Lacking this prior knowledge, those engaged in the construction of this remarkable line have done their very best to avoid mistakes and unnecessary expenditure, and the result is wholly creditable to the Office which employed them. The Treasury is sometimes unsympathetic towards scientific research, but the Treasury, after all, is only an exponent of the national will. It is the nation—the Empire—at large which is so indifferent to the value of scientific research, more especially in the domains of anthropology, zoology, botany, geology, and meteorology, that it cares little for the scientific examination of its territories, new and old. Some of this work can be done by private enterprise and generosity. But much might be accomplished by the Government if the Treasury would but agree. I am not asking for an expenditure of a million sterling per annum, or of even one of those unconsidered hundred thousand pounds cheerfully spent without blinking on an armed and punitive expedition. Twenty thousand pounds wisely expended on three scientific expeditions in West Africa, East Africa, and British Central Africa would probably give us all the information we require as to the products, soils,

minerals, natural history and human races of our tropical African dominions.

A NUMBER of prizes, varying in value from 800 to 8000 francs, are offered by the Belgian Royal Academy of Medicine for researches in various branches of pathological and medical science. The largest prize is offered for discoveries relating to the diseases of the nervous centres, with special reference to epilepsy, and for a really valuable discovery, such as a curative remedy for epilepsy; two premiums, one being of 5000 francs, may be given in addition to the prize of 8000 francs.

WE have received from Mr. J. Baxendell the report of the Fernley Observatory, Southport, for the year 1901. Mr. Baxendell continues his useful experiments and comparisons with the view of improving the records of self-recording instruments, especially those obtained from anemometers of various patterns. We quote the following climatological data from this important observatory:—Extremes of shade temperature, 88°·4 in July, 19°·1 in January and December; highest solar temperature, 129°·1, in August. Total rainfall, 26·7 inches, nearly 7·5 inches below the average. Bright sunshine (Campbell-Stokes recorder), 1738 hours. The report contains an interesting comparison of climatological statistics with upwards of fifty other health resorts.

MR. W. E. COOKE, Government Astronomer of Western Australia, has published a paper on the climate of that colony, from observations made during the years 1876–1899, containing a large number of valuable tables showing the monthly means and extremes of the various elements, illustrated by maps. The latter show that the records refer mostly to stations on or near the coast, and that the inland districts are, to a great extent, still unrepresented. In addition to the climatological tables, general descriptions of the types of weather most frequently experienced, and of the climate, with especial reference to that of Perth, are given in the text, and will be found very useful to all interested in the meteorological features of the country. Taking Perth to represent the south-west and south coastal stations, the mean monthly temperature is 64°·9, the highest extreme being 116°·7 and the lowest 31°·2. The mean annual rainfall is 32·9 inches. Within the tropics, records of 110° are not infrequent, the absolute maximum being 123°, at Onslow, in February, 1897. Thunderstorms, accompanied by heavy rain, are frequently experienced; the heaviest fall ever recorded was 36·49 inches, near Cossack, on April 2–3, 1898. On the other hand, only 0·73 inch was recorded in this district during twenty months ending January, 1892.

A NEW application of the electric furnace which may prove to be of great practical importance was described by Mr. C. B. Jacobs in a paper read before the New York section of the Society of Chemical Industry. The raw material for most of the barium compounds in common use is barytes, the natural sulphate, and this is usually converted into other barium compounds by treating it with coal or coke in a reverberatory furnace and then working up the crude barium sulphide thus obtained. It has been found that when barium sulphate and sulphide are heated together in suitable proportions at the temperature of the electric furnace, the sulphur is completely eliminated as sulphur dioxide and barium oxide remains, the conversion being so complete that only 2 to 3 per cent. of barytes remains unacted upon, as against 25 to 45 per cent. by the older process. By lixiviating with water and crystallising out, barium hydrate is obtained at once, containing only about 1 per cent. of impurities, chiefly barium sulphydrate. From this all the other barium salts are readily obtained. The electrical energy required for this process is got from the Niagara Falls, and the plant in use at the present time is turning out sixty tons per day. The fields into which it is finding its way are the tanning industry, the white pigment and dry colour trades, the purification of water for industrial purposes, and general manufacturing chemistry. The largest consumption, however, is in the beet sugar industry, for the recovery of the sugar remaining uncrystallised in the molasses. Barium hydrate is an ideal substance for the softening of water for boiler purposes, and its general introduction in place of the methods at present in use is only a question of price.

THE structure and design of electric automobiles are at present attracting much attention from electrical engineers. Sir H. P. Maxim in a lecture recently delivered before the Automobile Club of New York, commented on the progress made in the design of accumulators. The capacity of the cells per kg. of battery weight has been doubled, while the life of the plates has been increased 25 per cent. by the improvements made within the last three years. The best type of accumulator cell can now be utilised for running 8000 kms. before renewal of the plates is necessary. The electric automobile, in Maxim's opinion, is superior to all other types of automobile for general use. It is only likely to be supplanted by the petroleum or light spirit type of vehicle, where economy is the chief consideration, or where the distances to be covered are beyond the range of the electrically propelled car. Many of the latest types of electric automobile possess motors designed to act as dynamos for recharging the battery when the car is running downhill. A German engineer, Th. Müller, of Nuremberg, has been investigating the reality of the advantages claimed for this type of vehicle, and the details of his inquiry will be found in the *Zeits. f. Accumulatoren und Elementen-kunde* for March 1, 1902. The increased amount of copper required for motors, intended to act under such conditions as dynamos, and the greater complexity of their design, are held by Müller to quite counterbalance the gain of 10 to 15 per cent. which is all that results in the distance capacity of the cars.

A STATISTICAL comparison of developments of German and British trade in recent years is made in a long article in the *Times* of April 3. Though the writer seeks to show that there is little cause for uneasiness, he admits that Germany has advanced more rapidly than Great Britain in many departments of industry and commence. Especially is this true as regards chemical goods and electrical machinery, but no particulars as to these advances are given. So many industries depend upon chemical science for their means of progress that the present advantage which Germany possesses in applied chemistry is likely to produce far-reaching effects. Upon this subject the writer remarks:—"Years of research and theoretical training had made the German chemist *facile princeps*. Even in Great Britain, in France and in the States most leaders of the chemical trades and most assistants are Germans by birth or training; of Germany the chemical trades are a speciality. The technical colleges had likewise bred a highly efficient army of electrical, metallurgical and mining engineers who would soon find ample scope for their talents. In addition, the German mind has always been scholarly by inclination and open by habit. The self-sufficiency and the indifference to foreign doings, so characteristic of the British trader, never have been features of the German. On the contrary, he has always been open to foreign influences, and eager to adopt foreign ways." In the metallurgical trades, also, it is stated that Great Britain has not kept abreast of the times. During the last ten years of last century our iron production only rose from 7,900,000 to 9,421,000 tons, or, say, 17½ per cent., whereas that of Germany went in the same interval from 4,658,000 to 8,143,000 tons, and, therefore, increased more than 75 per cent. If the rate of progress be maintained on both sides, the German iron production

will be greater than the British in about three years' time. The general conclusion reached is that though as a nation Great Britain has continued to advance, Germany has made more rapid progress.

THE observatory on the summit of Mont Blanc, such a familiar object to all who visit Chamonix, has furnished M. Jean Binot with the means for making bacteriological investigations at the highest altitude yet explored. His researches are published in the *Comptes rendus* of the Paris Academy of Sciences. As was to be anticipated, the air on the summit away from the observatory contains scarcely any bacteria whatever, only from 4 to 11 being detected in as much as a thousand litres, whilst in somewhat smaller volumes of air frequently none at all were discoverable. As a rule, at lower altitudes, the number of bacteria present increased; thus at the Plan de l'Aiguille 14, whilst at the Montanvert 49, were found in a thousand litres. Inside the observatory, in which M. Binot tells us he spent five days, from 260 to 540 microbes were found in the same volume of air; these bacteria were doubtless introduced during the temporary invasion of the building by M. Binot and his companions. The investigations were not, however, confined to the air on the top of the mountain, but included also bacterial examinations of freshly fallen snow, old snow, ice on the surface and below, glacier water, and mountain streams. Freshly fallen snow, even when sampled in large quantities, frequently contained no bacteria whatever, whilst in snow which had lain for some time usually only from one to two individuals were discoverable per cubic centimetre; at the foot of the glaciers the surface snow contained rather more, the number varying from 6 to 65 per c.c. at the Mer de Glace. Glacier water is usually very pure, and, like the glacier-ice from which it is derived, was found to contain a number of yeasts and some streptothrix; but whilst high up such water contained but from 3 to 8 bacteria per c.c., a stream at the foot of the Glacier des Bossons contained 95, whilst the water of the river Arve at Chamonix was found to have as many as 7550 per c.c. Altogether M. Binot examined 121 samples of air, ice, snow and water, and isolated no less than 300 different varieties of microbes, one-third of which number he was able to identify as having been already studied and described, and the residue are being carefully investigated by him at the present time. Of great interest is the author's remarkable discovery of a virulent race of pyocyaneus bacilli in ice on the top of Mont Blanc; he also isolated from water a vibrio highly pathogenic to animals. Even the alluring and beautifully clear and crystalline spring water on the Montanvert road was condemned by being found to contain a dozen virulent colon bacilli in a cubic centimetre. Doubtless this pollution was due to the herds of cattle which graze on the mountain pastures.

IN the *Biologisches Centralblatt* for April, Dr. A. Bethe makes a further contribution to the discussion as to the nature of the "homing" instinct of bees and ants.

PART vi. of the second volume of the *Annals* of the South African Museum is devoted to a revision of the species of certain groups of the scorpions of the country, in the course of which several new forms are described.

IN the April number of *The Entomologist*, Miss Sharpe completes her list of the butterflies and moths collected by Dr. Christy in Nigeria. It is remarkable that a species hitherto believed peculiar to Aden should recur in West Africa.

THE annual report of the Indian Museum, Calcutta, for 1900-1901, states that important progress has been made in the improvement of the exhibited series, in the cataloguing of the reserve collections, and in the exchange and distribution of duplicate specimens. The acquisitions have been numerous, and, for the first time, the exhibited specimens have been adequately labelled in large type. The plan of replacing stuffed and spirit specimens of snakes by coloured casts is being carried out as rapidly as possible. A gallery has been reserved for economic zoology. Mr. T. H. Holland, of the Indian Geological Survey, has joined the board of trustees, in place of Mr. R. D. Oldham, retired.

THAT acquired characters may be inherited is suggested by Dr. Kidd's investigations into the arrangement of the hair on the human forehead, of which an account is given in the April issue of the *Journal of Anatomy and Physiology*. Certain lines of divisions appear in most cases, which are regarded as derived from the style of "parting" adopted by the parents. In the same publication, Mr. W. L. H. Duckworth, from the study of certain peculiarities in the skulls of a gibbon and an aboriginal Australian, is led to believe that in certain respects the man-like apes have attained a higher platform of specialisation than man himself.

IN the *Entomologist's Monthly Magazine* for April, Mr. C. W. Dale gives an account of the occurrence of the "mazarine blue" butterfly (*Lycaena acis*, or *Nomiades semiargus*) in Britain. According to the author, no specimens have been taken in our islands for more than twenty years; it is suggested that its extermination there may have been due to the attacks of hymenopterous parasites, although there is no evidence that this was the case. Never abundant, the species has been recorded from twenty-one English and Welsh counties, in several cases only on the evidence of a single specimen.

A MEMOIR in the *Quarterly Journal of Microscopical Science* describes the results of an investigation into the morphology of the skull of the bony fishes, based on an examination of its development in the three-spined stickleback. In addition to noting many points connected with the details of skull-structure, the author, Mr. H. H. Swinnerton, finds that his study of the anatomy and developmental history of the head-skeleton shows that the sharks and rays on the one hand, and the bony fishes and ganoids on the other, appear to have had a common ancestor, whose chief structural features are briefly indicated. It is added that the term "hyostylic," commonly used to indicate the mode of suspension of the lower jaw to the cranium in the latter group, does not adequately express the true state of the case. In another paper in the same journal dealing with what are commonly called "fishes," Dr. E. Warren discusses the structure of the teeth of the lampreys and hag-fishes. He remarks at the outset that those who regard these creatures as degenerate descendants of ordinary fishes would expect to find in their horny teeth remnants of the calcified structure of those of other vertebrates. He finds, however, no definite evidence of such degeneration, but adds that if they are actually degenerate they have reverted to a condition which probably preceded the development of the "placoid" scales of the sharks and rays.

AN interesting article in the March number of the *American Naturalist*, by Dr. H. P. Torrey, describes a peculiar phenomenon seen on the Californian coast during the past summer. Early in July a red streak was noticeable in the sea off San Pedro Harbour, which during the next few days approached the shore and divided into several patches of many acres in extent. On the 16th these patches reached the shore, where they were the cause of a most unusual display of phosphorescence. The discoloration and phosphorescence of the water were due to the presence of swarms of flagellate animalcules. "On the 20th, four days after the red (characteristically a muddy vermilion) streak had reached the shore, a most sickening odour arose from the water along the beach. During the night, on a beach about 400 feet long, a large number of animals were lef

by the tide. Among them were several hundred holothurians, several specimens of two species of sting-ray, two species of guitar-fishes (Rhinobatus), two cestracionts, two dog-fishes, a red perch, a large number of smelts, and several octopi." The "red water" occurred for at least two hundred miles along the coast and extended several miles out to sea; it had not disappeared at the beginning of September. Wherever it occurred food-fishes were scarce; but the small harbour-fishes and invertebrates of the "plankton" were unaffected. Towards the end of July, the animalcule Noctiluca appeared in swarms and devoured the animalcules of the red water. A somewhat similar visitation is reported to have occurred five hundred miles further south in the seventies, but has never before been known in California.

AN interesting case of peloria was furnished by a Cattleya which Dr. Masters showed at a recent meeting of the scientific committee of the Royal Horticultural Society. This abnormal flower appeared on a plant produced by crossing *Cattleya Schröderae* with *Brassavola Digbyana*. It showed three regular sepals, and alternating with these three petals, alike in size, colour and shape. The column was normal.

A RECENT number of *Science* records the proceedings of a number of prominent American botanists, now organised under the name of "The Botanists of the Central States." The meetings were held at the University of Chicago, under the chairmanship of Prof. J. M. Coulter. Among the papers read were the following:—F. C. Newcombe, "The sensory area of the roots of land plants"; H. L. Lyon, "The phylogeny of the cotyledon"; C. A. King, "Fertilisation and some accompanying phenomena in *Araiospora pulchra*"; H. S. Reed, "The ecology of a glacial lake"; R. A. Harper, "Binucleate cells in certain Hymenomycetes."

A CATALOGUE of plants has been received from Mr. H. P. Kelsey, the proprietor of the Highlands Nursery, N. Carolina, U.S. Mr. Kelsey has successfully undertaken to bring before Americans the wealth and richness of their native flora. The nurseries are situated at a height of 4000 feet, and naturally lend themselves to the production of such alpine or subalpine genera as Rhododendron, Kalmia, Tsuga, Leucothœ and Andromeda. To the cosmopolitan grower of interesting or little-known plants, this list of hardy American specialities will suggest many future possibilities.

VARIOUS explanations have been put forward to account for the production of cleistogamic flowers. No simple explanation has been offered which would cover the phenomenon in all cases; indeed, it is much more probable that they are formed in response to different stimuli, or for different purposes. In the second volume of the *Publications of the University of Pennsylvania*, Dr. C. H. Shaw discusses the formation of cleistogamic flowers in two American species of Polygala. One of these, *Polygala polygama*, produces both aërial and subterranean forms. The latter occur in early summer at the same time as the normal flowers, while the former are found later, on shoots which may have borne open flowers and which at this time develop a geotropic tendency. The morphological differentiation of the aërial cleistogamic flowers is intermediate between that of the other two varieties. The formation of the cleistogamic flowers seems to be correlated with the economic and rapid production of seed, for the normal flowers fail to a great extent to set seed, and require a longer time to mature it.

FROM two leaflets which we have received we notice that Kodak, Ltd., have two novelties which they have recently brought out. One of these consists of a kodak made especially for the use of glass plates alone, and fitted with the usual neat and simple movements and adjustments, many of which can be operated with one hand. These cameras are made in two sizes, for quarter and 5×4 plates, and both are fitted with Bausch and Lomb's lenses and shutters. The other new announcement is the number two stereo kodak for taking stereoscopic or single pictures $3\frac{1}{2} \times 3\frac{1}{2}$ in. on cartridge film. The camera is of the box pattern, measuring $8 \times 4\frac{3}{4} \times 6$ in., and requires no unfolding when a photograph is about to be taken. The shutters are ever-set, and are simultaneously operated for time or instantaneous exposures by separate levers. A third lever actuates three stops, and its position indicates which stop is in front of the lens.

THE additions to the Zoological Society's Gardens during the past week include a Caracal (*Felis caracal*) from South Africa, presented by Mr. F. C. Longbourne; a Suricate (*Suricata tetradactyla*) from South Africa, presented by Miss Philippe Stephenson; three Common Vipers (*Vipera berus*), British, presented by Mr. A. Old; a Diana Monkey (*Cercopithecus diana*) from West Africa, deposited; two Alpine Choughs (*Pyrrhocorax alpinus*), European, purchased; six Shaw's Gerbilles (*Gerbillus shawi*), three Black Swans (*Cygnus atratus*), bred in the Gardens.

OUR ASTRONOMICAL COLUMN.

TOTAL ECLIPSE OF THE MOON (April 22).—There will be a total eclipse of the moon on the evening of Tuesday, April 22, which will be partly visible in England. The total phase will be reached before moonrise at Greenwich (7h. 5m.), so that only the latter part of the phenomenon can be observed. The following particulars are for Greenwich mean time:—

	h.	m.
First contact with penumbra	3	50·3
,, ,, shadow	5	0·2
Beginning of total phase	6	10·2
Middle of eclipse	6	52·8
End of total phase	7	35·4
Last contact with shadow	8	45·4
,, ,, penumbra	9	55·3

The first contact with the shadow occurs at 89° from the north point of the moon's limb towards the east; the last contact at 60° towards the west.

Magnitude of eclipse (moon's diameter = 1) = 1·337.

In consequence of the eclipse taking place near the time of moonrise, it will be interesting, wherever the surroundings permit, to observe the setting sun and eclipsed moon simultaneously at opposite points of the horizon.

NEW VARIABLE STARS.—4 (1902) *Geminorum.*—Prof. Ceraski announces the variability of the star BD + 20°·1875, determined from photographs taken at Moscow. Its position is

$$\left.\begin{array}{l}\text{R.A.} = 7\text{h. } 32\text{m. } 37\text{s.}\cdot0 \\ \text{Decl.} = +\,20^\circ\ 45'\cdot3\end{array}\right\}(1855).$$

The magnitude is usually stated to be 9·0, and at present the brightness is increasing.

5 (1902) *Lyrae.*—In the *Astronomische Nachrichten* (Bd. 158, No. 3783), Mr. A. Stanley Williams announces the discovery of a new variable in Lyra whose coordinates are

$$\left.\begin{array}{l}\text{R.A.} = 18\text{h. } 56\text{m. } 12\text{s.} \\ \text{Decl.} = +\,37^\circ\ 18'\cdot7\end{array}\right\}(1855).$$

All the observations up to the present time are photographic, from plates taken with a 4·4-inch portrait lens.

The magnitude appears to vary between 10·6 and 12·0. From the dates of the minima it would seem to have a period of about two-thirds of a year, and in this case the next maximum should occur in or about the month of July 1902.

THE PHOTOGRAPHY OF DISTURBANCES IN AIR.

IN a paper read before the Royal Philosophical Society of Glasgow on December 4, 1901, and published in the *Proceedings* of the Society, Mr. H. S. Allen, of the Blythswood Laboratory, gives an account of "The Photography of Sound Waves and other Disturbances in Air." The method of striæ (Schlieren Methode) was devised by Toepler more than thirty years ago. This method makes it possible by suitable optical arrangements to render visible disturbances in which the refractive index differs but little from that of air.

One form of these arrangements is shown in the diagram, Fig. 1. The light proceeds from a source L which is as nearly as possible a straight line. In the figure this line of light is seen only in section—it is supposed to be at right angles to the plane of the paper. The light issuing from this source falls on a large concave mirror, M, by which it is brought to a focus just in front of the lens of the camera at I. One half of the lens is covered with an opaque screen, having a straight edge parallel to the image of the source, and the apparatus is arranged so that the image falls exactly on this straight edge Then, if all the adjustments are ideally perfect, no light at all will enter the camera so long as the medium through which the light passes is homogeneous. But supposing there is a region in the path of the light having a density different from that of the surrounding atmosphere, some of the light may be bent aside so as to enter the lens of the camera. Such a region is represented in section by the circle in the figure. It is supposed to be of greater density than the air around. The paths of the rays which have been refracted in passing through it are represented by the dotted lines. It will be seen that light traversing the lower portion is bent upwards and enters the camera, while light passing through the upper portion is bent downwards and falls still further than before from the boundary of the opaque screen. If the camera is focussed on this region of greater density, the lower part (that

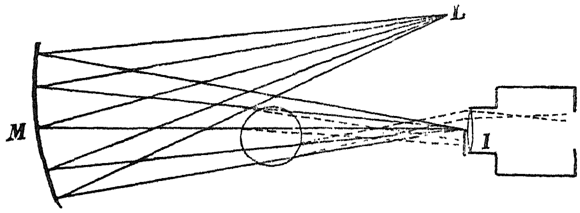


FIG 1.

is the upper in the camera, the image being reversed) will be illuminated, while the upper portion remains dark.

In working the method, the source of light and its image on the diaphragm must necessarily be of finite width, and the adjustments are made so that a certain fraction of the width of the image falls on the screen while the light from the remaining portion passes through the lens and gives rise to a uniform field. In these circumstances, the upper part of the region of greater density would appear dark against a light field. The sensitiveness of the method depends on the relative proportion of the light stopped by the screen and the light that enters the lens. For photographic purposes there must be a moderate amount of light to produce any effect even with the most sensitive plates, so that eye observations are considerably more sensitive. When it is desired to view the disturbances directly the camera is replaced by a telescope, or the image formed by the camera lens is examined by a suitable eyepiece.[1]

The mirror used was originally designed for a reflecting telescope. Its diameter was 18 inches, and it had a radius of curvature of 30 feet 3 inches.

One of the most striking applications of the method is the photography of sound waves—waves of compression set up by sudden electric discharges. Prof. R. W. Wood has taken a large number of photographs showing the behaviour of these waves (*Phil. Mag.* xlviii. p. 218, l. p. 148).

The arrangement of the apparatus is shown in Fig. 2. At the lower part of the diagram are the terminals, which supply an electric current at a high potential. The source of the current

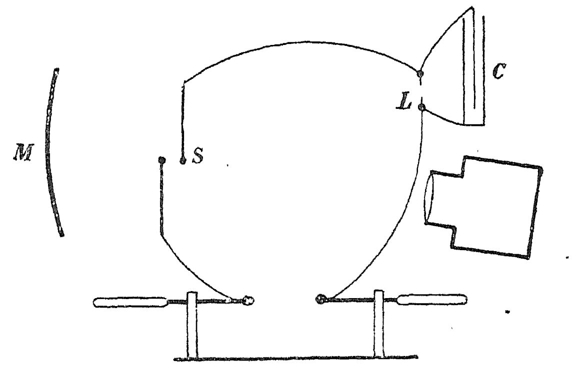

FIG. 2.

may be either an induction coil or an influence machine. From one terminal a wire is led to the spark gap placed in the path of the light travelling from the mirror to the camera. It is this spark which gives rise to the wave of compression to be observed, for convenience it may be termed the sound spark. The terminals are brass balls $\frac{3}{8}$ inch in diameter, and they are placed one behind the other, so that the light from the spark may not enter the camera. From this spark gap a wire is led to a second, which serves as the source of illumination, and is therefore provided with magnesium terminals. The circuit is completed by a wire from this point to the second terminal of the electrical machine. It is necessary that the light spark should take place somewhat later than the sound spark, in order to give the sound wave time to travel a sufficient distance from the terminals to be observed. To effect this a condenser is placed in parallel with the light spark, so that the light spark is delayed by the time necessary to raise the potential of the condenser high enough to spark across the gap.

A number of photographs were taken illustrating the reflection of a sound wave at surfaces of various forms and the effect of a diffraction grating. The original negatives were $\frac{7}{8}$ inch in diameter. They were enlarged to about three times this diameter for use as lantern slides.

The compression in one of these waves must be considerable compared with that due to an ordinary musical note. We may, perhaps, form a rough estimate of the amount of compression from the fact that the wave-fronts are seen at least as clearly as

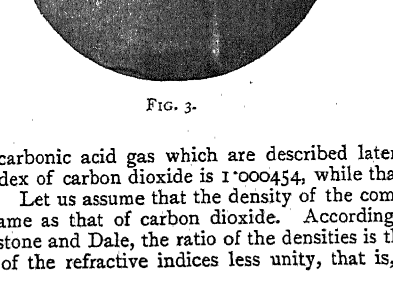

FIG. 3.

the jets of carbonic acid gas which are described later. The refractive index of carbon dioxide is 1·000454, while that of air is 1·000294. Let us assume that the density of the compressed air is the same as that of carbon dioxide. According to the law of Gladstone and Dale, the ratio of the densities is the same as the ratio of the refractive indices less unity, that is, in this

[1] A somewhat curious effect is observed with the optical arrangements just described which might form the basis of an optical illusion. If the eye is placed close behind the back of the camera (the ground glass screen being removed), the source of light with the apparatus for producing the light is distinctly seen, but when an eyepiece focussed on the back of the camera is employed, the apparatus for producing the disturbances in the air is seen with the mirror as a background. In the former case, the eye sees the real image of the source just in front of the lens and so close to it as to be practically unaffected by it, while the image which can be seen with the aid of the eyepiece is so near the eye as to be invisible.

case the ratio of 454 to 294, or, roughly, of 3 to 2. Thus, with these assumptions, the density in the wave-front is half as great again as the density of the undisturbed air. The wave resembles that caused by an explosion rather than that due to an ordinary sound.

Several attempts were made to see the train of waves due to a musical note, but on consideration of the facts just stated it is not surprising that they were all unsuccessful. The notes due to a shrill whistle and to a siren blown by a pair of foot bellows were both ineffective.

An attempt was also made to obtain a train of waves from the oscillatory discharge of a condenser through a circuit possessing

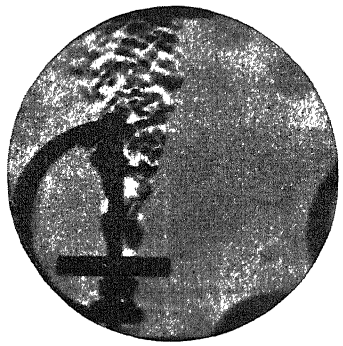

FIG. 4.

self-induction. A large Leyden jar and a coil of wire were inserted between the main terminals in Fig. 2. The frequency of the oscillation lay between the limits 7920 and 1800 vibrations per second, the wave-length of the corresponding sound-wave lying between 1·3 and 7·3 inches.

A number of photographs were obtained in which the first wave-front had travelled to such a distance that the second wave should have been clear of the terminals. But in none of them is any trace to be seen of a second wave. Thus, as an attempt to photograph a train of waves, this method too proved a failure.

Even as a failure the result is not without its interest, as it brings out very clearly the difference in character between the first discharge and the surgings that follow it when the spark is an oscillatory one.

In the words of Prof. Trowbridge, who has made a special study of oscillatory discharges:—"Photographs of powerful

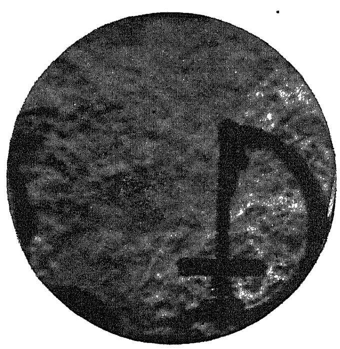

FIG. 5.

electric sparks lead one to conclude that a discharge of lightning makes way for its oscillations by first breaking down the resistance of the air by a disruptive pilot spark—through the hole thus made in the air the subsequent surgings or oscillations take place."

In the language of the modern ionic theory this would be interpreted by saying that the first disruptive discharge results in the production of a large number of free ions, and these ions offer an easy passage to the subsequent oscillations.

Since the refractive power of a gas is proportional to its density, and that in turn depends on the temperature, the method will reveal the presence of any region in the air whose temperature differs materially from that of the surrounding atmosphere. Such a case arises in every flame; the products of combustion rise from the flame as a column of heated gas, and this is revealed to the eye as a pillar of fire, or in the photograph as a pillar of cloud. The photograph shows the effect due to the flame of a spirit lamp (Fig. 3).

In order to impress the fact that what is here seen is not the flame, but the heated gas rising from the flame, a small fan was arranged which could be set in rapid rotation and so drive the hot gas all over the field of view (Fig. 4). The photograph (Fig. 5) shows the effect when it has been set rotating.

The flame of a Bunsen burner gives rise to a disturbance similar to that due to the spirit lamp, but more voluminous in character. The peculiar spiral form in which the column of gas rises before breaking up into a cloud is very noticeable in some of these photographs of flames.

A number of photographs were taken of jets of gas issuing from a narrow orifice. In one case the jet is formed by blowing heated air through a brass tube; in another it consists of carbonic acid gas issuing from the generating flask. In consequence of its great density, the gas begins to fall downwards soon after leaving the nozzle.

Several photographs were taken to show the mode of formation of a vortex ring of heated air. These rings were produced in the usual way by means of a box with an aperture in one side, and the opposite side formed of some elastic material. On giving this side a sharp tap, some of the enclosed air rushes out with the formation of a ring. In this case the air in the box was heated by placing a spirit lamp inside it so that the rings,

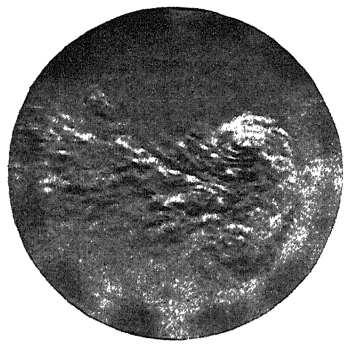

FIG. 6.

being formed of hot air instead of smoke, were quite invisible save by the use of the method of striæ. Some of these photographs are reproduced in the paper and are very instructive as showing the way in which the vortex motion is produced. The air appears first of all to issue from the orifice in the form of a column, but the tail is gradually left behind while the whirlpool motion of the head is accentuated. Finally, little is to be seen but the section of the ring itself, the spiral structure being strongly marked (Fig. 6). In some cases a circular, in others an elliptic orifice was used.

The appearance of some of these photographs showing vortex motion strongly recalls the published photographs of the nebulæ of the heavens.

THE TEMPERATURE OF INVERSION OF THE JOULE-KELVIN EFFECT FOR HYDROGEN.[1]

IN the year 1854 it was proved by Joule and Lord Kelvin that hydrogen on free expansion behaved differently to all other gases. Air, when allowed to expand from a higher to a lower pressure without performing external work, became cooled, the fall of temperature being proportional to the difference of pressure; hydrogen, on the other hand, became warmer. As is well known, the Joule-Kelvin effect has been applied by Hampson and Linde to the liquefaction of air in quantity, but since for hydrogen the effect is of opposite sign, it was obvious that the Hampson-Linde apparatus could not be directly applied

[1] By K. Olszewski. Translated from the *Bulletin* de l'Académie des Sciences de Cracovie. (December, 1901.)

to the liquefaction of that gas; a conclusion which is confirmed by this research. There seemed no doubt,[1] however, that after due modification the Hampson-Linde method would be applicable to the liquefaction of hydrogen, the necessary condition being that the gas should be cooled to below the temperature at which the Joule-Kelvin effect changes sign before entering the regenerator coil of the apparatus. Below this temperature the gas would become cooled on free expansion; as in the case of air in the ordinary Hampson apparatus, the cooling would be progressive and, were the heat insulation sufficiently perfect, would result in the partial liquefaction of the gas.

As is well known, Dewar and Travers (*Phil. Mag.*, 1901) have both succeeded in applying this principle to the production of liquid hydrogen. Both investigators employed as a preliminary refrigerant liquid air boiling under reduced pressure, and by this means cooled the hydrogen to $-200°$ C. The question now arises as to whether this is really necessary, or whether it would not be possible to liquefy hydrogen by allowing it to undergo free expansion after cooling it to a temperature less difficult to attain. The following investigation was undertaken in the hope of throwing some light on the subject and of determining the temperature at which the sign of the Joule-Kelvin effect changes.

Witkowski (*Roz. pr. Akad. krak.*, W.M.P. xxxv. 247; *id.* 1898) has applied two methods to the calculation of this temperature. The first method, based on the theory of corresponding states, gave $-46°$ C. as the temperature; the second method, in which Rose-Innes' formula was applied to the extrapolation of Joule and Lord Kelvin's experimental values at temperatures between 0° and 100° C., gave $-79°\cdot3$, a result which is nearer to that obtained by me experimentally, viz. $-80°\cdot5$. Rose-Innes' formula (*Phil. Mag.* [5], xlv, 228),

$$e = \frac{\alpha}{T} - \beta,$$

is purely empirical, but employing 64·1 and 0·331 as values for the constants, it reproduces the experimental results with remarkable accuracy.

Description of the Apparatus.

The hydrogen employed in these researches was obtained by the action of pure dilute sulphuric acid on commercial zinc; the gas was purified by passage through solutions of caustic soda and potassium permanganate, and finally through a tower containing pumice-stone soaked in mercuric chloride solution. The gas was collected in a zinc gasometer capable of holding 1200 litres, and from this was taken directly into the Whitehead torpedo-compressor, and compressed at 180 atmospheres into a steel cylinder of 13 litres capacity; in this cylinder was suspended a wire net containing sticks of caustic potash. During these operations every care was taken to remove all traces of air from the apparatus.

The expansion apparatus is shown in the accompanying figure. The steel cylinder, which contains the hydrogen under pressure, communicates by means of a copper tube with a manometer and with the tube *a* of the apparatus. The tube *a* is bent into a spiral *b*, which terminates in a valve *c*. The valve consists of a jet enclosed within a steel tube, perforated at the sides for the escape of the gas, which serves as a support for it. The valve spindle *d* passes through a gland packed with asbestos at *o*, and is screwed below *o* to fit the opening through which it passes, so as to allow of the valve being opened or closed. The valve is enclosed in a thin metal box *hh*, which is lined with chamois leather; the gas can escape by a tube *pi*, through the vertical portion of which an electric resistance thermometer is introduced. This instrument has previously been employed in the determination of the critical and boiling points of hydrogen (*Phil. Mag.* [5], xxxix. 199; xl. 202); the electrical connections are made by means of binding screws at *f* and *g*.

So as to be able to surround the coil *b* and the metal box enclosing the jet and thermometer with different refrigerants, the metal cap *nn* is cemented to the top of a thick-walled glass vessel *ll*. This in turn contains a thin glass vessel *mm*, insulated from the former at the top and bottom.

The refrigerating substances, liquid air, liquid ethylene, and solid carbonic acid and ether, can be introduced into *mm* through a T-tube passing through the cover of the apparatus, and by connecting one branch *k* with an exhaust pump the substance can be evaporated under reduced pressure and the temperature varied considerably. The temperature of the coil and jet can be roughly determined from the readings of a mercury manometer attached to the apparatus.

Method of Experiment.

The first experiments were made at about $-190°$ C., the temperature of liquid air. The initial pressure on the hydrogen was about 170 atmospheres, and on opening the valve for about five seconds a considerable cooling took place, the beam of the galvanometer attached to the electric thermometer moving 200 mm. over the scale. Using as a refrigerant liquid ethylene boiling at $-103°$ C., and with an initial pressure on the hydrogen of 150 atmospheres, cooling took place when the valve was opened, but to a less extent, the ray from the galvanometer moving only 30 mm. This was taken to indicate that the temperature of inversion lay considerably above $-100°$ C., and a series of experiments was next made about the temperature of solid carbonic acid and ether.

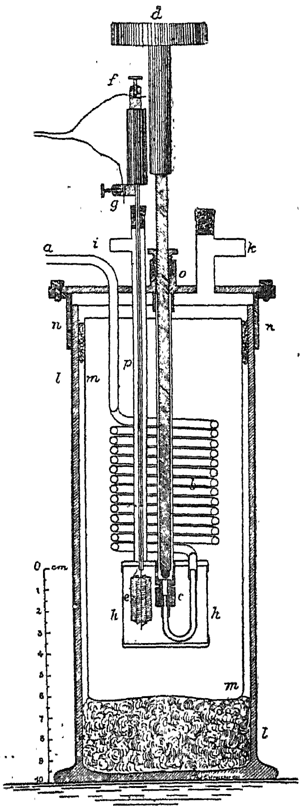

FIG. 1.

In this series twenty-five experiments were made, starting in each case with a temperature of $-78°$ C. and an initial pressure of between 117 and 110 atmospheres. To regulate the expansion, a small steel cylinder of 0·6 litre capacity was introduced between the main cylinder and the tube *a*; by filling the small cylinder from the main cylinder and closing the communication between the two before each expansion, the quantity of gas which escaped from the valve, and consequently the temperature change, was always the same. It appeared from these experiments that at $-78°$ hydrogen becomes warmer on free expansion, but only very slightly so, the ray from the galvanometer moving 3 mm. over the scale.

By reducing the pressure on the carbonic acid by careful pumping, the temperature was slowly reduced. At $-83°$, decided cooling took place on expansion, the galvanometer beam moving 5 mm. over the scale. By numerous trials it was found that the temperature at which the Joule-Kelvin effect became zero appeared to be at about $-80°\cdot5$ C.

Conclusions.

From these experiments it appears that the temperature of the inversion of the Joule-Kelvin effect for hydrogen lies about $-80°\cdot5$ C., a number which agrees very closely with that arrived at by Witkowski from the Rose-Innes equation ($-79°\cdot3$). This agreement makes it worth while considering the further application of this equation to other substances, particularly to air, and the application of the results to the calculation of the critical temperature of hydrogen on the basis of the theory of corresponding states. We have the following data:—

	Temperature of inversion of Joule-Kelvin effect.	Critical temperature.
Air	633° Abs.	133° Abs.
Hydrogen	192°·5 Abs.	—

[1] Kammerlingh Onnes (Leyden *Communications*, xxiii. 1896, 16) pointed out the possibility of liquefying hydrogen by means of Linde's apparatus, and stated the conditions, based on the theory of corresponding states, under which liquefaction can occur.

From this it follows that the critical temperature of hydrogen is 40°·4 or −232°·6 C., which is not far from the value which was found for it experimentally, viz. −234°·5 C. (*loc. cit.*).

From these researches it also appears that it is possible to liquefy hydrogen by the method of free expansion without cooling the gas to −200° C. Provided the heat insulation were sufficiently perfect, it should be necessary to cool the apparatus only to −100°, a temperature which could be attained by means of solid carbonic acid evaporating under reduced pressure, before allowing the hydrogen to expand. M. W. T.

THE RADIANT POINT OF THE APRIL LYRIDS.

THE moon being full on the evening of April 22 this year there is little prospect that the shower of Lyrids will assume prominence as a visible spectacle. It should, however, be carefully looked for on the night following April 21, for, notwithstanding the bright moonlight, it is probable that a few fine Lyrids may be observed if the weather is clear. The maximum formerly occurred on April 20, but 1900 not having been a leap year, the epoch of the shower has advanced one day, and must be looked for on April 21.

There is strong evidence to show that the radiant, like that of the Perseids, moves eastwards with the time, but the Lyrid display is always short-lived and frequently of very feeble character. Moreover, cloudy weather sometimes hides the meteors, or moonlight may practically obliterate them, so that it is extremely difficult to determine the exact place of the radiant on several succeeding nights. The April meteors are rarely as abundant as the August Perseids, though there is always the possibility of a brilliant return of the former as in 1803, when they fell so plentifully that they could not be counted.

I have collected together all the determinations of the Lyrid radiant which I have met with during the last nine years, and they form a curious medley of positions from which it seems impossible to derive any very exact results:—

Date.	Radiant.	Meteors.	Observer.
1893 April 20	257° +46°	47	A. A. Nijland, Utrecht.
	271 +42		
	278 +39		
	292 +39		
April 20–21	267 +37	15	H. Corder, Bridgwater.
	276 +34	10	
April 20–21	266 +37	—	E. R. Blakeley, Dewsbury (reduced by Corder).

	278 +31		
	278 +37		
	280 +33½		
April 18	266 +33	4	W. F. Denning, Bristol.
April 21	270 +33	25	
April 18–21	261 +36	8	

It will be noticed that some of the observers give a multiple radiant, but that the individual positions compared from year to year do not present a good agreement. At Bristol the radiant has usually been very sharply defined, when the true Lyrids have been sifted from the large number of other meteors directed from showers in nearly the same region of the heavens. The position of the radiant on April 20–21 is at 271° + 33°, and presents a perfect agreement with the radiant point of Comet I 1861, with which the Lyrids have long been supposed to be associated.

Some of the positions included in the list represent showers in Hercules and other contemporary streams. Mr. J. C. W. Herschel, from his observations in 1901, regards the radiant as decidedly multiple, but I believe that further observation will negative this conclusion. There are a considerable number of other meteoric systems in play at the same epoch as the Lyrids, and these, combined with unavoidable errors of observation, must sometimes give rise to apparently scattered radiation and multiple radiants. W. F. DENNING.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

AT the annual graduation ceremonial of the University of Edinburgh on April 11, Prof. MacGregor, who delivered an address, stated that the suggestion to found a laboratory in memory of the late Prof. Tait had taken practical shape, and that a subscription of 1000*l.* towards this object had been received from an anonymous donor.

SCARCELY a week passes without the announcement in *Science* of generous gifts to institutions for higher education in the United States. The following are among the gifts recorded during the past few weeks:—Mr. J. D. Rockefeller has given 1,000,000 dollars toward the general endowment fund of the University of Chicago, and 250,000 dollars for the general needs of the University during the present academic year. He promised a gift to the Harvard Medical School of 1,000,000 dollars on the condition that 765,000 dollars were collected to meet the sum required for the removal and rebuilding of the school. About 600,000 dollars were subscribed in two weeks, and this was quickly increased to 821,225 dollars, which was more than sufficient to make Mr. Rockefeller's gift available. Mrs. Collis P. Huntington has given 250,000 dollars to the Harvard Medical School to erect a laboratory of pathology and bacteriology in memory of the late Mr. Huntington. Mr. J. Stillman has given 100,000 dollars for the establishment of a chair of anatomy in the same school. Mr. Rockefeller has given 5000 dollars to Washington and Lee University, thus completing the fund of 100,000 dollars for a memorial to the late President William L. Wilson, in the form of an endowment for the chair of economics and political science. Barnard College, Columbia University, has added 500,000 dollars to its endowment, one half having been given by Mr. Rockefeller and the other half having been collected as a condition of this

gift. Harvard University has received three large bequests: 450,000 dollars from the late Mr. George Smith, 100,000 dollars from the late Mr. Robert C. Billings, and 100,000 dollars from the late Mr. Jacob Wheelock. Mr. Wheelock also bequeathed 100,000 dollars to Clark University, and Mr. Billings bequeathed 100,000 dollars each to the Massachusetts Institute of Technology and the Boston Museum of Fine Arts. The University of Wooster, Wooster, O., successfully completed a campaign to raise 140,000 dollars in order to secure two large conditional gifts, 100,000 dollars by Mr. Andrew Carnegie and 50,000 dollars by Mr. L. H. Severance, of Cleveland. By the will of Mrs. Lila Currier, 50,000 dollars will go to Columbia University and 100,000 dollars to Yale University upon the death of Mr. Edward W. Currier.

AN address on "The Profession of Teaching," delivered recently at Kendal by the Ven. J. M. Wilson, Archdeacon of Manchester and formerly head-master of Clifton College, has been issued by the Kendal *Mercury and Times*, and it will do a good service by directing attention to desirable objects of education. A school preparation should be of a kind which will foster the desire and develop the power to overcome difficulties; it should give self-reliance and sufficient knowledge of scientific principles to enable the pupil in after life to understand changing conditions and see their trend. Above all, school work should encourage the spirit of inquiry which finds delight in making new observations and experiments with whatever resources are available. The principle upon which Humboldt constructed Prussian education a century ago was: "Whatever we wish to see characteristic of our nation we must first implant in our schools." Remembering this, the teacher's aim should be to give the pupil an observant eye, alert curiosity that inquires into phenomena and their causes, the habit of accurate expression, and varied interests; for then whatever work is afterwards taken up will be satisfactorily done. Archdeacon Wilson strikes the fundamental note of true education in the following remarks from his address:—"The soldier may know all the campaigns of great commanders, from Alexander the Great to Lord Kitchener; but his knowledge avails little unless he has cultivated inventiveness and resource that meets wholly new conditions. The existence of our nation may depend some day on the nerve and originality of the officers of our navy. Every war is a new one; and the next will be utterly unlike the last or the present. It is the same in commerce. The new problems, with combines and international unions, with a shrunken world and new modes of transit, are not like the old. It is the same with agriculture, with mechanical and chemical industries, with engineering. Everything is new, and new every day. It is the same with philosophy and critical studies and theology. It is emphatically the same with statesmanship, municipal and imperial. What utterly new problems in international politics, in international economics and in domestic finance does the world present to-day. Assuredly if we would prepare our scholars for life, the supreme intellectual preparation is found in methods which evoke the faculty, the originality, the mental resourcefulness of our pupils." It is for us to see that the subjects and methods of teaching in our schools are such as promote the development of these qualities, for national progress depends upon them.

SOCIETIES AND ACADEMIES.

LONDON.

Physical Society, April 11.—Prof. S. P. Thompson, president, in the chair.—Dr. R. A. Lehfeldt exhibited an electric heater. The apparatus consisted of a vacuum jacketed glass tube, containing water which was boiled by passing a current through a platinum spiral immersed in the liquid. Tap water is preferable to distilled water, because the small electrolytic action in the former case causes the boiling to proceed quietly. Different temperatures can be obtained by using other liquids.—Mr. Grant exhibited and described an apparatus for vapour pressure measurements. The liquid of which the vapour pressure is required is introduced into the vacuum of a syphon barometer. This is mounted alongside an ordinary syphon barometer, and the upper extremities of both are surrounded by a bath, which can be kept at any desired temperature. The levels of the mercury in the open tubes are then adjusted until the upper mercury surfaces are at the same level. The vapour pressure is then measured by the difference of level in the open tubes. By a simple modification it is easy to investigate the vapour pressure of a liquid in the presence of air. The two chief advantages of the method are (1) the simplification of the temperature correction and (2) the wide range of temperature over which it can be employed with the use of a small bath. Prof. Callendar referred to the advantages of the apparatus, and said that it appeared specially suitable for elementary laboratory measurements.—Mr. J. T. Morris showed an experiment illustrating the use of kathode rays in alternate current work. The usual form of Braun tube was used, the rays falling upon a luminescent screen and forming a blue spot. A solenoid conveying an alternating current was fixed near the tube. The varying magnetic field caused the spot to oscillate about its mean position. To determine the maximum value of an alternating current, a switch should be arranged to rapidly replace the alternating current by a continuous one. The continuous current is then adjusted until the maximum excursion of the spot is the same as before and the value of the current read off from an ammeter in the circuit. For accurate work, the frequency of the discharge from the induction coil exciting the tube should be adjusted until it is almost exactly in synchronism with the alternating current. The unsteadiness of the spot of light in the zero position limits the accuracy of the measurements. Mr. Morris has tried to reduce this unsteadiness by using an earthed aluminium diaphragm instead of a glass one.—Mr. Morris then showed an experiment on the growth of electric currents in an inductive circuit. An E.M.F. of 0·8 volt was applied to a coil wound on a ring-shaped laminated iron core. When the current had attained its steady value, the E.M.F. was reversed and the variations of the current strength shown by an ammeter. About twenty seconds were required for the current to attain its maximum value in the opposite direction. A secondary coil was also wound upon the same core, and the effect produced upon the growing current by the closing of this secondary circuit was shown. Mr. Morris has determined curves of growth for different currents, and he showed how similar curves could be used to determine experimentally the hysteresis loss in transformers.—Mr. Croft showed some apparatus and devices useful in teaching. The method of determining graphically the focal length of a lens from the distances of conjugate foci from the centre was illustrated. The graphical solution of a quadratic equation was also shown. An apparatus for producing and demonstrating the properties of three-phase currents was exhibited and described. Mr. Croft then showed crystals illustrating the five regular solids, and an electric lamp with the filament in one plane useful for optical work. The flatness of a piece of plate glass can be tested with a scribing block. The point is adjusted to touch the glass in one position. By breathing on the glass and moving the block about it is easily seen if the point leaves the surface.

PARIS.

Academy of Sciences, April 7.—M. Bouquet de la Grye in the chair.—Note by M. de Freycinet accompanying the presentation of a work on the principles of rational mechanics.—On the differentiation of Fourier's series, by M. Leopold Fejer. In general the trigonometrical series, which is obtained by differentiating term by term the Fourier's series of a function $f(x)$, is divergent in the cases which occur most frequently in its applications. A special case of Fourier's series is considered in the present paper, which, when differentiated term by term, is always simply indeterminate, and with the exception of the limits 0 and 2π has for its sum $f'(x)$.—On the conditions of stability of automobiles on curves, by M. A. Petot. Formulæ are developed showing the amount of time necessary to pass from one curvature to another. A study of the fundamental conditions arrived at in this paper leads to the conclusion that it is the neglect of these which is the true cause of a number of serious accidents which have been attributed to a faulty steering gear.—Oscillations peculiar to networks of distribution, by M. Brillouin. The theorem deduced by M. Pomey in a recent number of the *Comptes rendus* was announced and demonstrated fifty-one years ago by Helmholtz.—On the relation $L + S/T = Q/T = K$, by M. de Forcrand. The molecular latent heat of volatilisation of ammonia is calculated by the formula of Clapeyron from the data of Regnault, and this is applied to the proof of a theorem that in all physical and chemical phenomena the heat of solidification of a molecule of a gas is proportional to the absolute temperature of volatilisation under a pressure of 760 mm. of mercury.—On the classification of the atomic weights

of neon, argon, krypton and xenon, by M. H. Wilde. The author assumes, without proof, that the atomic weights of this series should be represented by the members of the series $7nH$, where n is 3, 6, or 9. This would give the atomic weights as neon, 7 (9·96); nitrogen, 14 (14); argon, 21 (19·96); krypton, 42 (40·78); and xenon, 63 (64), instead of the experimental numbers given in brackets.—On a type of compounds of glucinum, by M. H. Lacombe. The compounds are of the type A_6Be_4O, where A is the radical of a fatty acid. Particulars are given of the preparation and properties of the formate, acetate, propionate, isobutyrate, normal butyrate and isovalerate. All attempts to prepare the normal salts of the type BeA_2 were fruitless.—On the constitution of the chlorhydrins, by M. Marc Tiffeneau. The author has applied the synthesis of chlorhydrins from magnesium alkyl bromides and mono-chloracetone to determine the constitution of the chlorhydrins obtained from olefines and hypochlorous acid. The rule given by Markownikoff, that in the fixation of HClO on olefines the hydroxyl group attaches itself to the carbon possessing the least hydrogen, as generalised by Krassousky was verified in the experiments described.—On the nitration of furfurane, and on a derivative of nitrosuccinic aldehyde, by M. Marquis. The nitration of furfurane in solution in acetic anhydride opens up the ring with the formation of a monacetin of nitrosuccinic aldehyde. By the action of pyridine upon this, the ring is again closed and mono-nitrofurfurane is produced.—On a new mode of preparation of oxygen, by M. George F. Jaubert. The peroxides of sodium or potassium are compressed with the theoretical quantity either of a soluble permanganate or hypochlorite, or a trace of a nickel or copper salt. Oxygen is produced from these cubes in the cold by the action of water.—Mendel's law and the heredity of pigmentation in mice, by M. L. Cuenot. Up to the present all researches on Mendel's law have been carried out on plants, and it is not known whether this mode of heredity is met with in animals also. Experiments were therefore carried out with white and grey mice, and it was found that the progeny obtained by crossing these was invariably grey. The result of crossing with these grey mongrels was in complete accord with the theory.—On the structure and mode of multiplication of the flagellæ of the genus Herpetomonas, by M. Louis Leger.—On the *Daniellia* of Western Africa and on their resinous products, their relation with the *Hammout* or incense of the French Soudan, by M. Edouard Heckel.—On the seismic influence of the Armorican folds in the north-west of France and in the south of England, by M. F. de Montessus de Ballore.—On a new application of the principle of chrono-photography and on the construction of isonomal barometric charts, serving for the kinematographical study of the general movements of the atmosphere, by M. P. Garrigou-Lagrange. A series of charts showing the isobars over a given area at sufficiently short intervals of time may be regarded as instantaneous photographs representing the several phases of a movement. A series of charts issued by the Signal Office at Washington has been treated from this point of view, and a number of charts obtained which can be used in a hand kinematograph.

DIARY OF SOCIETIES.

THURSDAY, April 17.

Royal Institution, at 3.—The Oxygen Group of Elements: Prof. J. Dewar, F.R.S.

Society of Arts, at 4.30.—Recent Developments in Punjab Irrigation: Sidney Preston.

Linnean Society, at 8.—The Anatomy of Todea with Notes on the Affinity and Geological History of the Osmundaceæ: A. C. Seward, F.R.S., and Miss Sybil O. Ford.—On the New Zealand Phyllobranchiate Crustacea, Macrura: G. M. Thomson.

Chemical Society, at 8.—Oxonium Salts of Fluoram and its Derivatives: J. T. Hewitt and J. H. Tervet.—The Influence of certain Acidic Oxides on the Specific Rotations of Lactic Acid and Potassium Lactate: G. G. Henderson and D. Prentice.—(1) The Amounts of Nitrogen as Ammonia and as Nitric Acid, and Chlorine in the Rain-water collected at Rothamsted; (2) The Amounts of Nitrogen as Nitrates and Chlorine in the Drainage through uncropped and unmanured land: N. H. J. Miller.

FRIDAY, April 18.

Royal Institution, at 9.—The Autocar: Sir J. H. A. Macdonald.

Epidemiological Society, at 8.30.—Smallpox Hospitals and the spread of Infection: Dr. Thresh.

Institution of Civil Engineers, at 8.—The Erewash Valley Widening and Toton Sidings: H. C. M. Austen.

Institution of Mechanical Engineers, at 8.—The Standardisation of Pipe Flanges and Flange Fittings: R. E. Atkinson.

MONDAY, April 21.

Victoria Institute, at 4.30.—Iceland, its History and Inhabitants: Dr. J. Stefansson.

Society of Arts, at 8.—Glass for Optical Instruments: Dr. R. T. Glazebrook, F.R.S.

TUESDAY, April 22.

Royal Institution, at 3.—Recent Methods and Results in Biological Inquiry: Dr. A. Macfadyen.

Institution of Civil Engineers, at 8.—*Discussion*: Locomotive Firebox Stays: F. W. Webb.

WEDNESDAY, April 23.

Institution of Civil Engineers, at 8.—"James Forrest" Lecture: Metallurgy in Relation to Engineering: Sir W. C. Roberts-Austen, K.C.B., F.R.S.

Society of Arts, at 8.—Opto-technics: Prof. Silvanus P. Thompson, F.R.S.

THURSDAY, April 24.

Royal Society, at 4.30.—*Probable papers.*—On Skin-currents. Part III.—The Human Skin: Dr. A. D. Waller, F.R.S.—Antarctic Origin of the Tribe Schœneæ: C. B. Clarke, F.R.S.—A New Interpretation of the Gastric Organs of *Spirula Nautilus* and the Gastropods: J. E. S. Moore and W. B. Randles.

Royal Institution, at 3.—The Oxygen Group of Elements: Prof. J. Dewar, F.R.S.

Institution of Electrical Engineers, at 8.—Problems of Electric Railways: J. Swinburne and W. R. Cooper. (Adjourned discussion).—Form of Model General Conditions, for use in connection with Contracts for Plant, Mains, and Apparatus for Electricity Works. As drafted by a Committee.

FRIDAY, April 25.

Royal Institution, at 9.—X-Rays and Localisation: Dr. J. Mackenzie Davidson.

PRACTICAL ZOOLOGY FOR BEGINNERS.

Leitfaden für das zoologische Praktikum. Von Dr. Willy Kükenthal. Zweite, umgearbeitete Auflage. Pp. viii+304; 169 illustrations. (Jena: Fischer, 1901.) Price 7 mk.

THE character of a work on practical zoology for beginners will differ fundamentally according to the particular point of view of the author. If the attainment of a thorough grasp of the organisation of a few animals be held to be the best means of developing the capabilities of a beginner, we are naturally led to the type-system of which Huxley was the pioneer, and his "Practical Biology," used conjointly with Prof. Howes' biological atlas, will remain a classic.

The German school, on the contrary, has developed another system; it gives the beginner at once a general outline of the animal kingdom, and concurrently a large number of animals are superficially examined.

There are arguments that can be advanced for either system. The broad outline of the animal kingdom provided by the German laboratories tends to arouse the interest of the student, and it is undoubtedly worth while to sacrifice much to accomplish this end; for without intelligent interest very little need be expected from the pupil. On the other hand, it must be admitted that such a system of instruction can too readily degenerate, and the result on the student's mind is likely to be but a confused assemblage of ill-digested facts. It may well be doubted whether a cursory glance over the whole animal kingdom constitutes as valuable a training for the future investigator as a thorough study of a few well-selected types.

In our universities we have to satisfy the needs of three classes of students:—(1) those seeking a general scientific education, (2) the future investigator and specialist in zoology, (3) the future medical man. The endeavour to deal with all three classes of students in the same manner cannot be wholly satisfactory; but a student beginning the study of zoology will probably not at first have the intention of becoming an investigator, and it would in practice be very difficult, or impossible, to separate the first two classes of students. Accordingly we must be content with arranging separate courses for the general student and the medical student.

The work by Dr. Kükenthal is primarily intended as a practical aid in the laboratory for the general student beginning his subject. The opinion as to how far the author has succeeded in his difficult task will greatly depend on the particular bias of the individual teacher. That the book has had a certain measure of success in Germany is evinced by the fact that the first edition appeared only three years ago.

The book begins with a rather meagre account of the apparatus required and of the general manipulation of the microscope. The body of the work consists of twenty chapters, each of which is divided into three parts:—(1) practical instruction in manipulation and the material required, (2) an outline sketch on the subject of the chapter, (3) a special description of one or more types.

The first chapter deals with the elements of histology. In the outline sketch, the nature of a cell and the general characters of tissues are shortly described. In the special description an amœba, white blood-corpuscle of the frog, egg of mussel and examples of the various tissues are very briefly introduced. The fact that a nucleus is capable of dividing is only just mentioned, although surely even a beginner ought to be shown preparations illustrating karyokinesis.

Each of the remaining chapters deals with one group or several allied groups of animals, and at the beginning of every phylum there is given a descriptive classification. The chapter on the Protozoa begins with an excellent account of events taking place in a hay-infusion, then in a single page the general characters of the group are summarised, while in the special description of types we find representatives of most of the more important classes of Protozoa; but the Foraminifera and Sporozoa are omitted. The Hydrozoa are also dealt with satisfactorily; the special descriptions include the following instructive series:—Hydra, Tubularia, Cordylophora, Clava, Tiara, Obelia, Liriope, Aurelia and Nausithoë.

The difficulty of such comparative treatment increases greatly as we pass to the more complicated Metazoa, and the author's accounts of the various groups tend to be decidedly unequal. Thus there is a brief description of the groups Bryozoa and Chætognatha, and among the Mollusca the genera Chiton and Sepia are included; yet of the Crustacea there is only Daphnia and a rather inadequate account of the crayfish. Also, in a book of this character the student might surely be somewhat further introduced to such larval forms as Trochosphere, Nauplius and Pluteus than by the mere mention of their names.

The chapters on the Vertebrata are the least satisfactory of the book. In some seventy pages we find Amphioxus, perch, frog, lizard, pigeon and rabbit. It may be doubted whether such an abridged account could be of much use to the beginner, and the descriptions take more after the method of a text-book than of a practical guide for the student in the laboratory. Inserted here and there are a few directions as to dissection, but without the constant aid of a demonstrator it is certain that an ordinary student could make but little of them. There are practically no figures of the vertebrate skeleton, blood-systems or nerves.

With the exception of the vertebrate section, the book is well illustrated with good figures, which appear in most cases to have been selected with much care. The appearance of one incorrect figure may be noticed. The series of diagrams after Boas (Fig. 38) showing the supposed stages in the degeneration of the medusa into a sporosac do not correspond to facts. The sporosac represents the degeneration of the whole of the medusa, and is not simply the persistent manubrium. There are a considerable number of original sketches which bear the impress of being drawn directly from dissected specimen, and are consequently especially useful to the student. The original drawings of the starfish and sea-urchin deserve particular mention.

In the opinion of the reviewer, we are in need of a compromise between the English and German methods of dealing with the beginner, in fact, a work intermediate in character between Huxley's "Practical Biology" and

the present book. Such a work need not necessarily greatly exceed the "Leitfaden" in bulk, for the classifications, excellent though they are, and the general summary of the different groups might safely be left to the lecturer or text-book. This, together with the omission of some of the less important groups, would allow space for more practical instruction in manipulation and for a somewhat fuller treatment of most of the different types described, more especially of those of the vertebrates.

On the whole, it may be said that the present work bears the stamp of originality; the style is clear and the descriptions are terse and generally accurate, and if in a future edition Dr. Kükenthal should see fit to remodel his book in such a manner as suggested, it would be welcomed in our colleges as a valuable and much-needed aid to the beginner in the laboratory. E. W.

FERMENTS AND FERMENTATION.

Ferments and their Actions. By Carl Oppenheimer, M.D., Ph.D., and translated and amended by C. Ainsworth Mitchell, B.A., F.I.C. Pp. xii + 343. (London: C. Griffin and Co., Ltd., 1901.) Price 7*s.* 6*d.* net.

THERE are few subjects more interesting and at the same time more difficult than the study of ferments and their actions. But many students, and not a few original workers, shrink from the study of ferments owing to the great complexity of the subject. A book, therefore, which aims at treating the subject in a concise and intelligible manner must inevitably attract a wide class of readers.

The author very properly points out that it is impossible to understand any of the problems relating to fermentation unless there be formulated some definition of a ferment *per se* and some simple conception of the process of fermentation. With this object, in the second chapter the writer gives us what he considers a simple definition of the notion ferment:—

"A ferment is the material substratum of a peculiar form of energy, which is produced by living cells and adheres more or less firmly to them without having its activity bound up with the vital process as such; this energy is in a condition to bring about the liberation of latent (potential) energy of chemical substances and its conversion into kinetic energy (heat, light), in such manner that the chemical substance is so changed in the process that the new substance or the sum of the new substances produced possesses a smaller potential energy (*i.e.* a smaller heat of combustion) than the original substance."

It must be confessed that, however scientifically perfect this definition may seem to be, it will not impress the average reader with the idea of its simplicity. But the distinguished author goes on to elucidate the different heads of this definition, and in so doing makes clear even to the lay reader many vital points bearing on this difficult subject.

The following frank acknowledgment of the ignorance which underlies all our conceptions of the ways and means by which fermentative processes develop their activity is worth quoting in full:—

"We must simply resolve to regard fermentative actions as special phenomena of the ominous 'catalytic' processes from which their differentiation is required by the fact that they are produced by living cells. Catalytic action is nothing more than a scheme of despair under which we may group chemical reactions which, while possessing a certain similarity in their course, cannot, without further knowledge, be explained by our simple chemical theories. With the advance of our knowledge, we have naturally been able to assign many phenomena which were formerly regarded as catalytic to simpler chemical laws, so that this useful idea has undergone a considerable limitation in its applicability. At the same time we must not forget that in its essence even the theory of simple chemical decompositions and of chemical affinity is, as regards our theoretical knowledge, only one vast enigma; that we have only been much longer accustomed to deal with these conceptions as indispensable fundamental axioms without being able to approach them otherwise than metaphysically, which also holds good in a still wider sense of the conceptions of matter and force in general."

Chapter iii., on the chemical nature of ferments, is well worth the most careful perusal. It is the fault of the subject, not of the writer, that it makes stiff reading. In this chapter the author points out the uselessness of such vague expressions, which lead nowhere, as that there are in ferments "fragments of protoplasm" endowed with "residues of vital force." Gautier's dissolved cell hypothesis is very ably discussed.

The influence of external factors on the action of ferments is concisely dealt with in chapter iv., and chapter v., on the mode of action of ferments, is perhaps the most interesting in a book all of which is full of matter of absorbing interest and importance.

But it is impossible within the scope of this short review to touch on more than a fraction of the points in the work, which will repay study by both the layman and the expert in this subject.

A. C. HOUSTON.

OUR BOOK SHELF.

Civil Engineering as applied in Construction. By Leveson F. Vernon Harcourt. "Longmans' Engineering Series." Pp. xv + 624; with 368 illustrations. (London, New York and Bombay: Longmans, Green and Co., 1902.) Price 14*s.* net.

THIS book, as the author states in the preface, consists of a concise grouping together of the various branches of constructive civil engineering.

A book that attempts to deal in a single volume with the vast range of subjects embraced in civil engineering must necessarily be more in the nature of an encyclopædia than a series of treatises on the subjects dealt with; and the descriptions of the works selected as examples are, therefore, necessarily limited to as small a space as is possible for the elucidation of the various subjects, and for indicating the practice followed in the execution of constructive works; but what is given is of a thoroughly practical character, and the subjects are very fully illustrated. The author has not taken up space by dealing with theories, or by giving elaborate formulæ.

The information given has been derived to a very large extent from *Proceedings* of the Institution of Civil Engineers, of which the author gives full acknowledgment.

The book should be of great use to an engineer when called upon to deal with constructive works of a character that he has not had previous experience of, as indicating the various ways in which constructive requirements have been treated. To students of engineering it will be of value in directing attention to the principles forming the

basis of design and construction, and by indicating the different ways in which these principles have been applied in practice.

The volume may, in fact, be regarded as a guide-book to what has been done, but its usefulness would have been enhanced if more frequent references had been made to the sources from which complete information on the different subjects could be obtained, or if a list of the works in which the subjects have been treated had been given at the end of each chapter. It is true that in such matters as harbours, docks and canals, with which the author is most conversant, the references from which the information is taken are plentifully given; but these are principally to the author's own works, and no mention is even made of the works on these subjects that have been published within the last few years in "Longmans' Engineering Series," of which this book forms part.

Besides a general introduction, the subjects are dealt with under five heads, and include (1) materials employed in construction; preliminary arrangements for carrying out work; excavation; dredging; pile-driving; cofferdams; foundations; piers of bridges; roads and street-paving. (2) Laying out and formation of railways; bridges; viaducts; tunnels; permanent way; light railways and tramways. (3) Control and regulation of rivers; canals and canalised rivers; ship canals; and irrigation works. (4) Docks, river quays, harbour works; lighting coasts and channels; land reclamation and coast protection. (5) Sanitary engineering, including water supply and sewerage works.

Rural Reader—Senior. By V. T. Murché. Pp. 292. Price 1*s.* 9*d.*

The Teacher's Manual of Object Lessons for Rural Schools—Senior. By V. T. Murché. Pp. xxiii+396. (London: Macmillan and Co., Ltd., 1902.) Price 2*s.* 6*d.*

THE schoolmaster in the country is just now very much in want of a text-book to guide him in giving that kind of instruction which is variously termed "nature knowledge" or "rural economy"; such elementary observation and reasoning applied to common things, as will stimulate the child's mind and yet serve as an introduction to agriculture or horticulture later. Mr. Murché was ready with two text-books very soon after the circular from the Board of Education in 1900, and now comes forward with two more for senior children, a reading book for school use and a parallel series of object lessons set out for the teacher's benefit.

The scope of the books is extensive enough—a little chemistry and botany, a few discourses on farming, then comes a considerable section on insect life, with chapters on fishes, reptiles, trees and ferns to the end. The get-up is excellent, nice type and plenty of pictures, so that any child will enjoy the varied course of the reader, and the teacher may get many excellent hints from the object lessons. But how fatally does the author miss the whole spirit of the work, which is to make the child see and think and find out things for himself. From beginning to end of the book the child is being told in dogmatic fashion scraps of information about natural objects of the most unequal degree of importance. The book is a typical compilation; in each subject the man who knows will detect, if not mistakes, yet that want of proportion, that emphasis in the wrong place, which mark the writer at second hand.

For example, on p. 63 the children are made to compare the flower of the Deadly Nightshade, *Atropa*, with the potato flower, to show them how a garden plant may have wild relations. In the first place, there is little superficial resemblance between the flowers, and *Atropa* is a really rare and casual plant in England, whereas every hedgerow contains the "Woody Nightshade," poisonous enough and with flowers that are unmistakably the fellows of the potato flower. Again, we notice on p. 127 an account of the mole cricket, with a picture; how many collectors, not to speak of children, have ever found a mole cricket? And so the book goes on through the whole gamut of animated nature; our feeling in the end is one well known to examiners, "I suppose I must allow some marks for this, but——" We have not yet found the text-book for country schools, and we are afraid that Mr. Murché's is just a sufficiently middling substitute to block the way of the real article when it comes.

A. D. H.

Poultry Management on a Farm. By Walter Palmer, M.P. Pp. 94. (Westminster: Archibald Constable and Co., Ltd., 1902.) Price 1*s.*

THE object of this work is to show that poultry in considerable numbers can be kept on an ordinary farm with profit. Mr. W. Palmer, M.P., on land of about 200 acres, has established a poultry department. 350*l.* have been expended in buildings and the necessary appliances, a skilled manager with three assistants have been appointed, and the results of three years' work are very fairly given in this well-printed and well-illustrated, but very cheap, volume. Whether the results are such as will induce many other agriculturists to go into the pursuit or not may be regarded as doubtful, but the volume is well worthy the attention of those who are interested in the matter. Poultry farms pure and simple have long been known to be visionary, those institutions at present going under that name not being utility poultry farms, but places for the rearing and sale of fancy stock at fancy prices. Mr. Palmer is an enthusiast in his subject, and it is needless to say that his work presents the results of his experiments in the most favourable light, but this is obviously done with a good motive and in an exceedingly truthful manner. Many practical farmers would, however, object to his figures. Nothing is charged for the annual depreciation and wear and tear of the plant. The annual value of the manure of the two thousand birds is estimated at 100*l.* Moreover, the author states that if the ninety thousand farms in England were all to keep poultry on the plan recommended by himself, the profit arising from this source would be no less than four and a half millions a year to the British farmer. These statements will be differently estimated by different readers.

Lectures on the Lunar Theory. By John Couch Adams M.A., F.R.S. Edited by R. A. Sampson, M.A Pp. 88. (Cambridge University Press, 1900.) Price 5*s.*

WE are glad to see that the famous lectures of Adams on the lunar theory have been published so as to be readily accessible to all. They have been well edited and most lucidly presented to the reader. Prof. Sampson naturally, however, did not feel at liberty to extend the subject-matter of the lectures, so that the work remains in a slighter form than Prof. Adams would, perhaps, himself have cared to publish it.

This being so, we are led to ask—What class of readers does this book specially cater for? We do not think the students, for the book cannot compete with Dr. E. W. Brown's treatise, nor would it be of any great value to the calculator who should wish to develop afresh correct expressions for the moon's coordinates, for the chief difficulties here consist in the correction of approximate solutions, a section to which only four pages (pp. 30–33) is devoted in the present work, and, moreover, the action of the planets is not considered. Perhaps, then, the class that will find this book most interesting are the astronomers, who from time to time want to refer to small portions of the theory and obtain numerical values for some of the quantities that occur. This was, perhaps, not the design of the work, but we can recommend it as serving this purpose thoroughly.

Lectures and Essays by the late William Kingdon Clifford, F.R.S. Edited by Leslie Stephen and Sir Frederick Pollock. 2 vols. Pp. 410, 342. (London: Macmillan and Co., Ltd., 1901.) Price 10*s*.

It is neither upon his popular lectures nor upon his crude essays in metaphysics that Clifford's permanent reputation is based. But it is not surprising that they still find numerous readers; they are so free from pedantry, so engagingly frank, so evidently the work of a man who sought truth with a really passionate desire. We may smile at Clifford's theory of "brain-stuff," which is easily demolished by the very same kind of criticism which he himself applied to "The Unseen Universe"; we may feel justly astonished that a mind so penetrating in many ways should believe that consciousness is a complex of elementary feelings, which can separately exist as things in themselves; we may regret the occasional bitterness of his invectives, even while we remember that they were inspired by a hatred of priestcraft and superstition. But with all this, when we turn again to these fresh and stimulating pages, and when we read once more Sir Frederick Pollock's graceful and generous introduction, we can understand how Clifford charmed and impressed his contemporaries, and how keen was their sorrow at his premature death. It is, perhaps, not altogether fanciful to compare Clifford's fate with that of Robert Louis Stevenson; in each case a reaction has followed the too partial praise of admiring friends, and this disparagement is again being corrected by a more dispassionate criticism.

Teoria delle Funzioni Analitiche. By Giulio Vivanti. Pp. 432. (Milan: Ulrico Hoepli, 1901.) Price 3 lire.

"A pocket guide to the Theory of Functions," may strike many pure mathematicians as being a rather startling innovation. But the rate at which mathematical knowledge is added to every year makes it increasingly difficult for a mathematician to acquire a thorough acquaintance of more than a very limited range of study, and if the physicist, for example, has to derive his information on the theory of functions from large treatises and scattered literature, "life is too short" and the work is crowded out by other matters.

The book is divided into three parts, the first containing the elements of the theory of groups, the second the general theory of analytical functions, while the third contains a sketch of certain recent developments of the theory of functions. Prof. Vivanti bases his treatment on Weierstrass's methods. At the end is a list of 218 books and papers dealing with the subject, all for the very small price of half-a-crown.

It is much to be wished that a reaction may be set on foot in this country against the over-elaboration and specialisation of mathematical text-books by the publication of a series of small handbooks similar to this little Italian treatise. The need for a change of this kind is well illustrated by a copy of the 1860 edition of Routh's "Rigid Dynamics," which the present writer has just acquired. It bids fair to be much more useful in teaching a certain class of student than the modern large two-volume editions.

Graduated Exercises in Elementary Practical Physics. By C. J. Leaper. Pp. iii + 264. (London: Biggs and Co., 1901.) Price 2*s*. 6*d*.

This contains the usual elementary exercises in physics, and it is not obvious what special advantages it offers. Many of the diagrams are very bad, and the printing is poor. Examples are given for the students to follow; thus we find the product in Boyle's law carried to six significant figures, and the latent heat of fusion of ice to five figures. How often are we to cry out against this?

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* Nature. *No notice is taken of anonymous communications.*]

The Education Bill.

The suggestion in your editorial memorandum last week on this subject is one for which there is a remarkable precedent in the history of educational controversy. That suggestion is to the effect that, having regard to the complexity of the subject, to the fact that the urgent need of our time is the organisation of secondary and higher instruction, while the condition of our primary instruction is, on the whole, satisfactory and but for the demands of the voluntary schools would not require any material change at all, it would be well to divide the Bill into two parts and to press forward during the present session the enactment, with due modifications, of that part which affects intermediate and scientific education, and so to leave the part relating to elementary education for fuller consideration another year.

This course would be precisely similar to that adopted by Mr. W. E. Forster in 1869, the year before the Elementary Education Act. He had been a member of the Schools Inquiry Commission, which had recently issued a memorable and most comprehensive report, the work largely of the late Lord Lyttelton and the present Archbishop of Canterbury. As Vice-president of the Council, he introduced the Endowed Schools Bill, which was designed to deal with the whole problem of secondary as distinguished from elementary instruction. The Bill was divided into two parts, the former providing for the urgent need of the moment, the reform of the ancient and often obsolete and useless endowed foundations, and the latter constituting central and local authorities for the coordination and improvement of all classes of secondary schools—private, proprietary and municipal—for the registration of teachers, for the provision of needful schools, and for the construction of a coherent system of secondary education for the whole country. But it happened then, as it is happening now, that such a large and far-reaching proposal touched many interests and involved many difficulties, and that it proved impossible to pass the whole Bill in one session. So Mr. Forster wisely abandoned the second part of the Bill, and resolutely secured the passing of the first. The Endowed Schools Act thus simplified and placed on the statute book is still in force, and has proved to be one of the most beneficent of modern Acts of Parliament. It created a special Commission, with power to inquire into the history and resources of educational foundations, to revise and modernise their statutes and deeds of gift, to reform the governing bodies, and to secure the permanence and increased public usefulness of educational endowments generally. Other attempts have been made in subsequent years to deal piecemeal with the larger projects of educational reform contemplated by the Government of 1869; but it remains on record that if an attempt had been made to enforce the enactment of the whole measure, the Endowed Schools Act, which has proved of such signal public service, would never have been passed.

Without renewing any discussion as to the merits or demerits of the new Bill, it may interest your readers to be reminded of the precedent thus set more than thirty years ago. If that precedent were followed in the present case, it would at least give an opportunity to the newly constituted local authorities to deal at once with technical and secondary education, and thus to gain a new title to public confidence. The public would then be enabled to judge, after one or two years' experience, of the expediency of entrusting to these bodies the larger and more difficult task which the present Bill proposes to hand over to them—the virtual reconstruction of the whole existing system of elementary education. J. G. Fitch.

Athenæum Club, April 22.

I find myself in entire agreement with the views expressed by Principal Lodge in the last number of Nature. And if any practical illustration were needed to support them, I think ti is afforded by the invaluable work which has been done for secondary education in the county of Surrey.

Until the County Council took the matter up, the educational destitution of western Surrey as regards secondary schools was

deplorable. There was no provision for either carrying on the education of the best boys at the primary schools, or for educating the large class of sons of artisans and others for whom the primary schools were insufficient and such private-adventure schools as existed altogether inadequate. As a governor of the Richmond School I am able to speak with confidence of the remarkable success which has attended its establishment.

As regards Surrey I do not see, therefore, that the Bill will put us in a much better position than we are at present. But the present crying need is that primary education should be dealt with on the same lines. It would, in my opinion, be a real disaster if the part of the Bill relating to it were to be dropped, as has been proposed in these pages.

In the Borough of Richmond the arrangements for primary education can hardly be described as other than chaotic. I am by no means persuaded that the establishment of a School Board would make matters much better. We might gain something in one direction at the cost of losing all chance of coordinating our arrangements for primary with those for secondary instruction. The one should dovetail into the other, which it is little likely to do if they are in different hands. I am wholly at a loss to see why an organisation which has solved one problem should not be able to solve both.

Kew, April 21. W. T. THISELTON-DYER.

The Dangers of Coral Reefs to Navigation.

IN consequence of a paper which I recently read before the Royal Geographical Society on "The Formation of the Maldives," I have received several letters from officers of the mercantile marine. These lead me to believe that the danger incurred by too closely approaching coral reefs and islands is not generally perceived. Further, I have myself seen large passenger steamers coasting round the south of Minikoi Atoll within 300 yards of its encircling reef. Indeed, one large liner was so close in that the look-out man at the mast head could not have failed to see the bottom. The practice of approaching so near *where unnecessary*—to enable passengers to get a good view of the land and reef—is one attended with considerable danger and greatly to be deplored.

It is generally known that most reefs on their seaward faces slope gradually from their edges to 25–50 fathoms, and then more steeply to 100–200 fathoms. The breadth of this inner slope or reef-platform varies in the Maldives and Laccadives from half-a-cable to half-a-mile. Its surface, especially down to 20 fathoms, is extremely uneven, great buttresses and masses of rock arising to within a few fathoms of the surface. Such rocks are very generally covered with green corals or dark-coloured, calcareous algæ, so that except in absolutely calm weather they may not readily be perceived. Further, isolated coral heads—separate coral colonies—may grow up on any rocks within about 20 fathoms of depth almost to the surface. I have in Maldivan lagoons been twice stranded on such heads, arising respectively from 8 and 14 fathoms. At the seaward ends of passages into atolls of the same group, where the conditions are not very dissimilar to those outside atolls, similar heads not infrequently grow from 15 fathoms or even deeper to within 2 or 3 fathoms of the surface. The tops of these are often only a few yards across, so small indeed that they may be easily missed in any survey, however careful.

It is apparent then that dangerous rocks may arise on any part of the reef-platform. The outer steep slope is often so precipitous that the edge of this platform is only separated by a few yards from the 100-fathom line. The latter is usually very carefully charted, but for safety liners and deep-draught steamers should pass well to seaward of it. J. STANLEY GARDINER.

Gonville and Caius College, Cambridge, April 20.

Rearrangement of Euclid Book I.

I HAVE always taken it for granted that the *chief*, if not the *only*, objection to Euclid's Elements as forming an introductory course in geometry is that a very large proportion of beginners *are unable to work riders for themselves*, and consequently they are reduced to the necessity of merely reading up the propositions in such a way as to be able to reproduce them more or less mechanically in the examination room.

This difficulty does not exist in algebra because, taking simple equations as an instance, it is easy by varying the numerical coefficients to furnish the beginner with an unlimited variety of *numerical examples* which, being all solved by the *same* method, do not present such difficulties as Euclid "riders," each of which is practically a separate problem or theorem requiring a *different* method of solution.

The wide gap between the reproduction of bookwork and the devising of methods of solving riders presents a serious obstacle to the progress of beginners. What I at present fail to see is how the gap would be bridged over either by a rearrangement of the propositions in Book I. or by any of the substitutes for Euclid which have been suggested of recent years, and I much hope that this letter may be the means of eliciting fuller information on the direct connection between the present unsatisfactory state of affairs and the proposed remedies. G. H. BRYAN.

Bangor.

The Morphology of the Pleuronectidæ.

ABSENCE from Liverpool has prevented me replying to Mr. J. T. Cunningham's criticisms of the work on the anatomy of the Plaice recently published by Mr. Johnstone and myself. The passage which Mr. Cunningham chiefly objects to is as follows:—"If [the dorsal fin] occupies the mid-dorsal line of the head, then it is obvious that the left eye must have actually passed through the substance of the head to reach the ocular side. This supposition, absurd as it may seem to us now, was in fact believed by such an observer as Steenstrup." In "correcting" this passage Mr. Cunningham says:—"The truth of the matter is that Steenstrup did not believe any supposition, absurd or otherwise, on the subject, but stated from actual observation that in certain larval Pleuronectidæ the eye of one side passed through the tissues of the head and emerged on the other side. The form in question was long known as Plagusia, and is now known to be the larva of Rhomboidichthys. The truth of Steenstrup's observations was fully confirmed by Alexander Agassiz at Newport, R.I."

Now on referring to Steenstrup's memoir again I find that it is Mr. Cunningham himself who has misunderstood that author. For whilst Steenstrup certainly observed an *apparent* passage of the eye through the head, he also *supposed* that the eye passed actually through the tissues of the head itself, as apart from those of the dorsal fin, which cannot, of course, be considered a part of the head. This is the theoretical deduction that I characterised as absurd, since it is needless to say that neither Steenstrup nor Agassiz ever witnessed so impossible a phenomenon. Indeed, both Agassiz and Ehrenbaum state, quite correctly, that the migrating eye lies between the base of the dorsal fin and the roof of the head, and therefore only "apparently passes through the head" (Agassiz).

The significance of the asymmetry of "Plagusia" has been made quite clear by the short but important paper recently published by Nishikawa. This paper renders almost certain the deduction which I think most morphologists would have drawn from Agassiz's work, viz., that the metamorphosis of Plagusia is in all essential respects similar to that of the Plaice. The fact that here the dorsal fin grows forwards *before* metamorphosis sets in has not affected the fundamental character of the torsion, for the migratory eye is, of course, *morphologically outside the head during the whole of its transit*. Nishikawa says, and very truly:—"In every case, the passage of the eye from one side to the other in flat fishes is morphologically along the dorsal surface of the head." The statement, therefore, to which Mr. Cunningham takes exception is absolutely correct, and it seems that, living remote from scientific libraries and doubtless unable to consult the original, Mr. Cunningham's memory has led him astray.

Mr. Cunningham's second point involves an academic issue that I must leave others to discuss. Prof. Mitsukuri once remarked to me, in connection with his having undertaken some systematic work, that he had temporarily abandoned the morphological pursuit of similarities, in favour of the systematic search for differences. Thus, whilst many systematists, with their taxonomic details, would widely separate the Pleuronectidæ from the Gadidæ (although Jordan and Evermann, whom we followed, do not), most morphologists, taking a much broader if less precise view of the question, would say that a Plaice was simply an asymmetrical cod-fish. And both may be right judged by their own standards. F. J. COLE.

Swarm of Velella.

THE brief note from Alassio by Mr. Isaac Thompson on the extent and density of a swarm of Velella off that coast this month recalls to my mind seeing a similar scene on each of two occasions when staying at that place in April. On each occasion of the swarm there was, as I well remember, a strong wind from the east; on each the shore became so thickly strewn with the organisms as to become unpleasantly odorous from their decay. CH. S. SHERRINGTON.

Felixstowe, April 19.

REFERRING to your correspondent's letter on the swarms of this little marine animal that strewed the shores of the Riviera di Ponente early in April, I was at Alassio and remarked that the wind had been easterly for some days before the advent of the swarm. Alassio is situated on a sandy bay facing the east; on the western side of the bay, two miles away, lies a fishing village called Laiguelia; here the Velella were in far greater numbers, thickly piled on the shore, thinning off gradually towards Alassio, while beyond Alassio, at the extreme eastern end of the bay, the Velella were comparatively thinly scattered on the sand. The clear horny oval disc over the little colony of polypes, with its diagonally-set, triangular sail, places Velella at the mercy of the winds; a shoreward wind blowing for several days must end in the wreck of the little "Barca di San Giovanni" (boat of St. John), as the Alassian fishermen call it. I am told it is usually in early June that the swarms are swept ashore, and then in immense numbers—far more than strewed the bay this April. The prevailing wind in summer at Alassio is easterly. ROSE HAIG THOMAS.

Habits of the Gar-fish and Mackerel.

BEYOND the fact that the bodies of other fish are occasionally pierced by them, no evidence seems to exist concerning the special function of narrow elongated jaws of the gar-fish (*Belone vulgaris*, Fleming). These fish are usually captured in drift nets along with mackerel, and there appears to be some vague idea among fishermen that they either guard or guide the mackerel shoals. In the cases on record where a mackerel or other fish has been pierced by the gar-fish, the upper jaw of the latter has usually been found broken off and remaining in the wound. This fact is inconsistent with the supposition that the normal function of the elongated beak is to be used as a spear, and there is no evidence that the gar-fish feeds on the flesh of large fishes.

Examination of the beak itself shows that the end of it is formed by the tip of the lower jaw, which is about half an inch longer than the upper. This tip is not hard and sharp, but soft and blunt; the upper jaw is narrower, and ends in a harder and sharper point. Thus the lower jaw is by no means adapted for use as a piercing weapon. Recently I opened the stomach of one of these fish landed at Newlyn, and found in it the partly digested remains of a slender silvery fish, which at the time I could not identify. The next day I opened a number of mackerel and found in some of them copepods and amphipods, but in nearly all remains of fish food, and in one, two specimens of the smaller sandeel (*Ammodytes tobianus*) only slightly digested. I was then able to satisfy myself that the fish on which the Belone had been feeding was also the sandeel, and I was impressed with the similarity in the structure of the jaws between the Belone and its prey. It then occurred to me that the proper function of the beak of the Belone was to penetrate the sand in pursuit of sandeels. The latter fish burrow into sand by means of the projecting lower jaw, and it is evident that the beak of the Belone is as well adapted for probing the sand, finding and seizing the sandeel, as is the beak of the woodcock for probing soft ground in search of worms and burrowing insects. The flexible tip of the fish's beak is doubtless a sensitive tactile organ, while the narrow toothed upper jaw is eminently fitted for seizing and holding the slippery and agile prey.

It seems very probable that special adaptation for the pursuit of sandeels in the sand explains, not only the peculiar beak of Belone, but also the elongation and structure of the whole body. Narrowing and elongation of the body are related in fishes and many other animals to creeping or burrowing habits. Probably, not merely the beak, but the greater part of the body of Belone also is thrust into the sand in pursuit of its prey, and this would explain why the dorsal and ventral fins are placed far back, so that the propelling apparatus remains in the water, and why the abdominal region is nearly cylindrical, with a somewhat flattened ventral surface, without dorsal or ventral ridges.

The fact that the mackerel were also feeding on sandeels further suggests a special reason for the association between mackerel and gar-fish. It is true that many predaceous fish eat sandeels when they can get them, but the jaws of the mackerel are not specially fitted for dislodging sandeels from the sand. In the early part of the year mackerel feed largely on copepods and other pelagic animals, having long, close-set gill-rakers through which they can strain the sea-water, like clupeoid fishes. In summer and autumn mackerel feed chiefly on small fishes which swim near the surface, such as the young of sprats, herring, gadoids, &c. But it seems probable that mackerel accompany the gar-fish in order to feed on the sandeels which leave the sand in their efforts to escape from their special enemy.

I have not yet made any observations on the food or habits of the saury-pike (*Scomberesox saurus*), but it is probable that, as in the case of Belone, injury to pilchards or other fishes by the beak of this fish is rather accidental than intentional. Couch and Matthias Dunn believed that the saury-pike was the enemy of the pilchard, and that it attacked the latter. When a number of both kinds of fish were enclosed in a seine, many of the pilchards had their eyes or bodies pierced by the beaks of the saury-pikes, but the latter are very active and violent in their movements, and if they were rushing about among a dense crowd of pilchards, the beaks could scarcely fail to pierce the latter. J. T. CUNNINGHAM.

Flinr Implements at Chelsea.

WHILE planting in the garden of this house last Wednesday, I turned up a small flint implement, an inch and a half long and an inch wide in the widest part. It is so thin and transparent, that it is possible to read large print through it. This is the second I have found, the previous one being angular and pointed. A. B. MARSHALL.

Belle Vue House, 92 Cheyne Walk, S.W., April 18.

The Misuse of Coal.

PROF. PERRY, in his manifesto in NATURE of March 20 (with which, subject to a reservation in respect of the following extract, I venture reapectfully to agree) says (p. 464):—

"For the heating of buildings Lord Kelvin pointed out long ago that the very law of thermodynamics which makes a heat-power engine inefficient makes it possible to obtain from one unit of energy the effect of 50 or 100 units by direct heating. . . Discover the energy engine and you multiply your power to heat buildings from coal, seventy and seven times."

May I ask if Prof. Perry adheres to the foregoing statement, and if so, ask him through you to kindly add some elucidation of it? SUBSCRIBER.

Derby, April 15.

"SUBSCRIBER" may be referred to § 196 of my book on "Steam," where I explain Lord Kelvin's suggestion and give a numerical example. I assume no better utilisation of coal than one gets from a gas engine using Dowson gas and practical conditions, and yet here are the two answers for one pound of coal:—

(1) By direct heating, all the heat of the coal being given to the air (it is unusual to give nearly so much), the air gets 8300 units (Centigrade pound) of heat.

(2) By using a gas engine and reversed heat engine, 37,620 units of heat are given to the air. This is only four and a half times and not the seventy-and-seven of which I somewhat rhetorically spoke. But with the perfect energy engine of the future we may get nearly six times what we get from the gas engine now. Also I considered an atmosphere at 10° C., the air to be heated to 20° C. for the warming of a building. If the rise of temperature is only 5 degrees we get twice the benefit.

It looks at first sight like a creation of energy, but this is not so. The reversed heat engine (some refrigerating machines work on this principle) receives work energy 1422 (specified in heat units); this work is converted into heat 1422, and the extra heat 36,198 is merely *transferred* from air at 10° C. to air at 20° C.

What is disadvantageous in the heat engine becomes advantageous in the reversed heat engine, whether it is used for heating or refrigerating. J. P.

A Correction.

In my letter *re* "Birds attacking Butterflies and Moths," in NATURE for March 6 (p. 415), there occur the words, "I conclude, therefore, that they were last year's birds, which knew and disliked *D. limniace.*" There is some slip here, for what I meant to say was, "I conclude, therefore, that last year's bird knew and disliked *D. limniace.*" This, it will be seen, agrees with the context; I only used one Babbler last year, and offered *D. limniace* to this only. F. FINN.

Indian Museum, Calcutta, March 27.

SOME SCIENTIFIC CENTRES.

IV.—THE HEIDELBERG PHYSICAL LABORATORY.

MOST travelled Englishmen are doubtless acquainted with the ancient town of Heidelberg, so famous for the beauty of its situation and the grandeur of its ruined castle. But far fewer know the charms of the long and romantic valley of the Neckar, at the almost sensational exit of which, from the Odenwald into the level plain of the Upper Rhine, Heidelberg stands. So also it is true that while most educated people connect Heidelberg with the great names of Kirchhoff and Bunsen and their epoch-making discoveries in spectrum analysis, it is only the special students who know how large in extent and how important in result and example is the work which has steadily gone on for many years in the physical laboratory in the Friedrichsbau.

Its small beginnings in the middle of the last century are marked by the name of Kirchhoff scratched on the window of what is now the private room of the senior assistant. From this window one may look out over the Rhine plain towards busy Mannheim, as Bunsen and Kirchhoff did one night when a fire was raging there, and they were able by spectroscopic examination of the flames to ascertain that barium and strontium were present in the burning mass. But the same window also looks across the Neckar to the Heiligenberg, along the slopes of which runs the "Philosophers' Walk," the chief of the many paths among the wooded hills around the town, which the two friends were wont to traverse in their daily "constitutionals." Bunsen is known to have said that it was during such walks that his best ideas came to him. One day the thought occurred, "If we could determine the nature of the substances burning at Mannheim, why should we not do the same with regard to the sun? But people would say we must have gone mad to dream of such a thing." All the world knows now what the result was, but it must have been a great moment when Kirchhoff could say, "Bunsen, I *have* gone mad," and Bunsen, grasping what it all meant, replied, "So have I, Kirchhoff!"

Kirchhoff's four-prism spectroscope, together with other apparatus of his, is preserved in the collections of the Laboratory, and well deserves the almost reverential awe with which it was examined by a certain foreign professor, who protested that objects of such historic interest should be kept in a fire-proof safe.

Kirchhoff, who in his later years suffered much from ill health, left Heidelberg in 1875 on his appointment as professor of theoretical physics at Berlin, where, by the way, he had no official laboratory, and carried on his experimental work (*e.g.* the research on the conductivities of the metals for heat and electricity) in the laboratory of his friend von Hansemann. His successor at Heidelberg was his former pupil, Quincke, who has been professor there ever since, and is now the "doyen" of German physicists, both by length of service—for though only sixty-seven he has been a professor for more than forty years—and by the amount and variety of his scientific work. It is true that this work has not been of the kind that gets into the newspapers, but the real students will certainly value it none the less on that account, and even the beginner in science has heard of "Quincke's Interference Tube" and his standard measurements of capillary constants. English students may well take some special interest in Quincke, for his personal relations with English men of science (*e.g.* Lord Kelvin and Sir Henry Roscoe) have been particularly close; he is never tired of dwelling with admiration on the achievements of Young, Faraday and Kelvin—and in the case of Young in particular of vindicating his priority in respect of many of the ideas in light and sound often regarded as original to Fresnel and Helmholtz—and nowhere have his own researches been more highly valued than in this country, as is shown by the long list of Universities (Cambridge, Oxford, Glasgow) and learned societies (from the Royal Society downwards) which have conferred their honours upon him.

Georg Hermann Quincke was born at Frankfort a. O. in 1834 of partly Huguenot extraction. One who has seen the diagrams, with circles worthy of Giotto, which he draws on the blackboard, or had experience of his apparently intuitive knowledge of the possibilities of the most various materials and mechanical processes, might well be inclined to regard this kind of power, so valuable to the physicist, as an inheritance from some skilful Huguenot ancestor. From 1852 onwards he studied at Berlin, and then for a time at Königsberg, attracted thither (with others, such as Kirchhoff and Clebsch) by the fact that F. E. Neumann was delivering the only course of lectures on mathematical physics then to be heard in Germany. Neumann's mathematical and experimental genius had considerable influence on Quincke, and it was here that the profound interest in molecular physics which has dominated his life-work was aroused in connection with the theory of capillarity. But Neumann allowed his pupils too little scope for originality, and Quincke removed to Heidelberg, where (in 1854) Kirchhoff had just been appointed professor of physics. Under him Quincke carried out (in 1856) his first physical research, an investigation of the lines of flow of an electric current from one point to another of a metal plate. With a plate made of adjoining semicircles of copper and lead, Kirchhoff's law of the refraction of currents was confirmed, viz. that the *tangents* of the angles of incidence and refraction are in a constant ratio, though, curiously enough, this ratio was not found equal to that of the conductivities of the two metals, as the theory requires, but only about half as great. During this time—in which Matthiessen and Roscoe were among his fellow students—Quincke also worked much with Bunsen, especially in gas and mineral analysis, and, indeed, his first published paper was on the red and grey gneiss of the Erzgebirg (1856). Doubtless the association with Bunsen did something to cultivate Quincke's native faculty for the ingenious adaptation of the simplest materials, of which more hereafter.

From Heidelberg Quincke returned to Berlin, "promovierte" in 1858, became "Privat docent" in 1859, in 1860 was appointed professor at the Royal Prussian "Gewerbe Akademie" and in 1865 "ausserordentlicher" professor at the University of Berlin, posts which he held till 1872. His courses of lectures included the only one in mathematical physics then given in Berlin. But as regards original work the young professor was much hampered by the fact that he had neither stores of apparatus nor even a decent library of scientific literature at his disposal. In both respects he was much aided by his friend Wilhelmy (of invert sugar fame), who possessed a good deal of apparatus brought from Paris, and by Mitscherlich. Before this Mitscherlich had introduced him to G. Wiedemann, and a beautifully kept juvenile note-book had led to his drawing the figures for some of Wiedemann's publications. How well he was capable of such work will be clear to all who have seen his lithographed sheets of instructions for practical work in use in his present laboratory, with their admirable diagrams.

With Wilhelmy's apparatus, and much which he constructed for himself, often out of the simplest materials, he was able to exhibit many of the chief optical experiments which could at that time be seen nowhere else out of Paris, and to inspect which some of the leading men of science in Berlin, such as the mathematician Kronecker, were glad to visit him. To take but one instance of his ingenuity in devising efficient substitutes for the complicated and expensive forms of apparatus generally used, we may mention his method of constructing a Fresnel's double mirror. Two equal plates of black glass are fastened to a suitable wooden slab by means of four wax pellets, two under the corners of the adjacent edges, and one each under the centre of the opposite ends of the plates. If now a thin sheet of glass is laid over the whole and gently pressed down in the centre, the two glass plates become inclined to one another at slightly less than 180°, forming— *experto crede* —a perfect Fresnel's mirror. In this way the students in his present "Praktikum" construct this piece of apparatus for themselves as required.

Quincke's settlement in Berlin was signalised by his discovery of the "Strömungsströme," or electric currents produced by the flow of liquids past solid walls, which is the inverse phenomenon to the "elektrische Fortführung," or transport by an electric current of suspended particles through liquids in narrow channels. This he examined in an extensive research, leading to the conclusion that both phenomena were due to electrification by contact of the liquid with the solid wall or the suspended particles. The range of cases in which electrification is produced by contact of dissimilar substances was thus largely increased, and *inter alia* it was shown that a bubble of air in contact with water carries a negative charge, a result which accounts for the interesting discovery of Lenard that in the neighbourhood of Alpine waterfalls the air is invariably strongly negatively charged.

To this same period belong two extensive series of researches in optics and capillarity respectively. The optical investigations, recorded in close upon a score of lengthy papers in *Poggendorff's Annalen*, deal with the most difficult questions connected with the optical properties of metals, the researches of Cauchy, Stokes and Jamin, and the behaviour of polarised and diffracted light in general. From among the results obtained we have only space to mention the discovery of "lamellar diffraction,"[1] the proof that neither Jamin's law of polarisation by reflection nor Stokes's theory of the polarisation of diffracted light is in accord with all the facts, the considerable addition to the theory of the diffraction grating, and the startling deduction from some of the work of the fact (long afterwards confirmed by Kundt and others) that the refractive index of silver and gold for sodium light is less than 1, a result which of course means that light travels faster through these metals than in air. It is an interesting fact that these researches were originally prompted by the hope of penetrating more deeply into the secrets of the molecular constitution of matter. Many of them were carried out by the help of thin metallic films deposited on glass. But these very films did not a little to show that capillary phenomena were likely to be more fruitful in this direction. One of the most elegant of modern researches is that in which (1869) he used a wedge-shaped film of silver deposited on glass to measure the range of molecular attraction, by determining the thickness of the silver film through which the capillary action of the glass on water in contact with the plate just vanished. The result was that the radius of the sphere of action of the molecules is about 50 $\mu\mu$ (*i.e.* about one-tenth of an average light-wave). This was the first effective attack on this profoundly interesting problem; the method remains the least exceptionable yet devised, and the result has been confirmed by the later researches of Sohncke (1890),[1] though Röntgen and others, by means of more questionable methods, have found a value many times smaller.

It will be convenient to speak of the capillary researches in a general view presently, but mention must be made here of the well-known acoustic interference tube. The invention of this (1866) was due to a case communicated to him by a doctor, in which a patient, whose hearing was being tested by sounding a tuning-fork at the end of a rubber tube leading to his ear, was found to hear better when the tube was pinched. This was the first of several forms of acoustic interference apparatus devised by Quincke, which have been used by his pupils for investigations on the velocity of sound under various conditions, recently, for instance, in air at high temperatures. From this research it appears that the ratio of the specific heats for air falls from 1·40 at 0° C. to 1·34 at 1000° C.

In 1872 Quincke was appointed to the chair at Würzburg, whence he was called in 1875 to fill Kirchhoff's place at Heidelberg. His work there has been marked by a long series of electric and capillary researches, and by a great increase both in the efficiency of the laboratory and in the number of students. Among those who have studied under Quincke or worked in his laboratory may be mentioned Profs. Lenard (Kiel), Braun (Strassburg), W. König (Frankfort), Max Wolf (Heidelberg), Precht (Hannover), and Willard Gibbs and Michelson of America. The work is still hampered by want of room and by the antiquated character of the building, which compares but poorly with the "Paläste der Physik" recently erected at several of the German Universities. But men are more than buildings, and Quincke has shown astonishing ingenuity in utilising the space and means at command to accommodate the 120 students who attend his "Praktikum."

It is perhaps in association with the practical work of his laboratory that Quincke is seen at his best. He maintains a constant interest in the doings of his "Praktikanten"; no student is too dull nor any experiment too simple to enlist his personal attention. His research students find him unfailing in advice and assistance of the most helpful kind. If he is on occasion "heftig," it is only to become kinder and more helpful than ever. He gives his time ungrudgingly to his "Colloquium" and "Seminar." In the latter (held in the summer Semester) he lectures at length on some classical research, the practical work in connection with which is then carried out by the students, and the theory reproduced and results recorded in full for his approval and criticism. The Colloquium (in the winter Semester) is a small society for the discussion of current physical research. Here one learns to admire alike the patient consideration he shows the "Vortragender" (even if the latter happen to be a foreigner stumbling through his task in the most deplorable German), the independence and originality of his own outlook on current theories, and his extraordinarily wide acquaintance with both the older and the most recent literature of physics.

His lectures deal with an unusually wide range of topics, and are illustrated, not merely by a large collection of diagrams mostly drawn, and where necessary coloured, by his own hand, but also by many experiments rarely exhibited elsewhere. To quote a few instances almost at random, it is not often that one has the opportunity of seeing Cornu's hyperbolas (formed by reflection of monochromatic light from the surface of a bent glass strip), or water spread out in a capillary film on the surface of mercury, or experimental proof of the fact that super-

[1] Precht (*Wied. Ann.* lxi.) believes he has found a similar phenomenon in the case of Röntgen rays.

[1] And by the investigation of R. Weber (1901) on oil films (referred to in Prof. Rücker's recent presidential address), which was carried out in Quincke's own laboratory.

saturated water vapour only condenses in presence of suitable nuclei, or the production of double refraction by electrostatic stress (Kerr effect) in liquids, or Faraday's pretty experiments on the electrolytic action of the current from a frictional machine, or the beautifully ingenious demonstration, by manometric measurement of the pressure of an air bubble between the plates of a condenser immersed in an insulating fluid, of the pressure perpendicular to the lines of force in the electric field and its relation to the difference of potential between the plates. This last experiment was originally devised by Quincke in connection with an important research on the dielectric constant (sp. ind. cap.) of liquids, which he measured in three different ways—the ordinary "capacity" method, the measurement of the attraction between the plates in air and in the liquid (*i.e.* of the force parallel to the field), and, as just mentioned, of the pressure perpendicular thereto. The three methods yielded results which were, on the whole, in very satisfactory agreement with one another and with Clerk Maxwell's theory, *e.g.* for CS_2 2·64, 2·67, 2·74 (square of refractive index for D line 2·69).

This was only one of a long series (1880–1888) of electric and magnetic researches. These dealt, *inter alia*, with the alteration in elasticity, volume and refractive power produced by electrification ("electric expansion" and electrostatic double refraction, with the suggestion that the latter may be explained by the former). Deserving of especial mention is the discovery of the changes in level of magnetic (and diamagnetic) liquids contained in the capillary limb of a U-tube placed in the magnetic field. These changes are due to the difference of the "magnetic pressures" perpendicular to the lines of force in the liquid and the surrounding gas (compare the electric case above); they are proportional to the susceptibility of the liquid and the square of the field strength, and if the latter be independently determined, the susceptibility is deduced. By varying the gas in contact with the liquid, the susceptibility of gases may be measured. A method similar in principle is applicable to solids in the form of wires or electrolytic deposits on suitable rods. When once the susceptibility of suitable liquids (ferric and manganese chlorides are among the best) has been determined, the method can be used with great advantage to measure the strength of magnetic fields.

All this opened a wide field of research, but space forbids us to dwell on the interesting developments respecting "atomic magnetism" and other points.

Quincke is probably most widely known by his researches in capillarity, which have been of the most extensive and laborious kind. For the fundamental liquids, as we may call them, *i.e.* water and mercury, he has made great use of the methods of flat drops, and of air bubbles in the liquid, and therewith found values of the surface tension somewhat higher than those obtained by himself and others in other ways, in particular (for water) by the well-known capillary-tube method. He regards these higher values as the more probable, and concludes that the angle of contact of water and glass is not zero, as usually assumed, and therefore the water does not rise so high in capillary tubes as it would if the angle actually vanished. He has confirmed this by devising methods for measuring this angle of contact both on flat surfaces and in capillary tubes, and thus shown that for water and glass the angle may be 20° or so. He has also proved how sensitive the angle is to slight and often imperceptible changes in the condition

Georg Quincke

of the surface. For water on cleavage surfaces of mica, for instance, it varies from 0° to 30° or more, according as the surface is quite fresh or has been exposed for shorter or longer periods to the air. By this principle of the variation of the angle of contact, and consequently of the size and appearance of small drops of liquid (water, mercury) deposited on a surface different parts of which are in imperceptibly different conditions, he has explained the formation of the curious "breath figures" and of Daguerreotype photographs. Daguerre discovered these through the accident of having left some of his silver iodide plates, which he had until then been unable to make permanent, in a cupboard where some mercury had been spilt. The vapour deposited itself in different-sized droplets on the different parts of the plate and gave a picture which could be made permanent.

The very extensive series of researches Quincke has made on salt solutions lead to the general result that the

surface tension of such solutions increases with greater concentration by a term proportional to the number of equivalent weights of salt in the solution. For fused solid substances he has measured the surface tension by the methods depending on the weight of falling drops, and on the size and form of drops formed on a flat surface. Employing, then, a quantity a^2 which he calls the "specific cohesion" of the substance (defined by $a^2=2$ [surface tension]/ density), he found the remarkable result that ("to a degree of approximation closer than that which holds good for Dulong and Petit's law of atomic heats") all pure substances fall into one or other of six classes the specific cohesions of which are in the ratio of $\frac{1}{2}$ (*e.g.* phosphorus, sulphur, bromides, iodides): 1 (*e.g.* Hg, Pb, chlorides, nitrates, sugars): 2 (*e.g.* water, Ag, carbonates, sulphates): 3 (*e.g.* Zn, Fe): 4 (K): 7 (Na). It may be noted that a^2 measures the capillary attraction of a fluid sphere of unit radius on unit mass at its surface. That this quantity for various fluids is proportional to 1, 2, 3 . . . is in remarkable contrast to the fact that gravitational attraction is independent of the nature of the substances involved.

One of Quincke's most interesting and characteristic researches relates to the motions produced in drops clothed with oil films when an alkali is brought into contact with the oil, forming soap, which locally disturbs the existing surface tensions and causes a movement of the drop. Quincke sees in this the explanation of the movements of protoplasm. To quote his own words, "Ich glaube gezeigt zu haben, dass der Zellinhalt (das Protoplasma und der Zellsaft) jeder Pflanzenzelle von einer dünnen Oelhaut bekleidet ist: dass dünne Oellamellen mit festem und flüssigem Eiweiss die Plasmamasse durchziehen, und dass durch Einwirkung des alkalischen Eiweiss auf das oelsäurehaltige Oel periodisch 'Eiweiss-seife' entsteht, aufgelöst und an der Grenze von Oel und umgebender Flüssigkeit ausgebreitet wird. Diese periodische Ausbreitung der wässrigen Lösung von Eiweiss-seife gab dann die physikalische Erklärung der im Innern der Pflanzenzelle beobachteten Bewegungserscheinungen." Quincke's most recent researches relate chiefly to his favourite problems of molecular physics, but are, for the most part, still unpublished.

Reference has already been made to the Heidelberg "Praktikum," or course of practical physics, for which Quincke has devised many ingenious forms of simple and cheap apparatus, which are yet capable of giving surprisingly good quantitative results. Here one may see an optical bench which, though chiefly made of a half-metre scale and some cork, sealing wax and glass strips, yet enables the student to make all the usual measurements with mirrors and lenses, without dark room, and with an accuracy equal to that obtainable with apparatus many times larger and more expensive. Again, Quincke has invented a form of reflecting galvanometer[1] which costs some fifty shillings in all, but is sufficient for all ordinary electric measurements, not merely for learners, but also for research students. Want of space forbids us to tell of the almost innumerable devices for solving just those problems which confront so many of our science teachers in England at this moment which the Heidelberg laboratory contains. A word may be spared for two seeming trifles which are astonishingly useful. One is the lidless box used as a seat, giving three different heights, according as it is placed on its short, long or open side. A few of these can be combined with a screw clamp or two in endless ways to serve as supports for apparatus, &c. The other is a form of trestle[2] (with the two slant legs at one end replaced by one vertical one), which is very convenient as a support for pendulums and other such apparatus.

[1] This, together with Quincke's invaluable "Cathetometer Microscope," is visible on the table behind the Professor's right arm in the photograph reproduced herewith.

[2] Visible on the right of the photograph.

It is much to be hoped that Prof. Quincke may see his way to publish his laboratory notes in book form, and if he would accompany such a book with directions for carrying out what a witty Heidelberg student described as "Quincke's cork-wax-pfennig system," he would be conferring a boon on many students and more teachers. But we fear it is hardly likely that the claims on his time as teacher and investigator will allow opportunity for this to be done.

EMILIEN JEAN RENOU.

M. RENOU was born at Vendôme, March 8, 1815, and, naturally, went to the Lycée there. He entered the École Polytechnique in 1835 and later the École des Mines, where he studied under Élie de Beaumont. He subsequently visited German universities for two years, especially the lectures of Gauss at Göttingen.

From 1839–42 he was attached to the Scientific Commission of Algeria and published a "Description Géologique de l'Algérie." In 1846 he was directed to collect all the information as to Morocco which he could find, and the result was a valuable work, "Description de l'Empire du Maroc." He made a second visit to Algeria, at his own expense, to verify previous geographical determinations.

In 1850 he resolved to devote himself almost exclusively to meteorology, and he was one of the founding members of the Société Météorologique in 1853. He has published numerous papers in its *Annuaires*. He acted as its secretary for eleven years, not consecutive, and no less than four times was elected to fill the office of president.

In 1868 he was one of the members of a committee, under the presidency of Charles Ste. Claire Deville, for the organisation of the observatory of Montsouris. After the events of 1870–72, this establishment was placed under M. Marié Davy, and M. Renou had to leave.

In 1872 he was officially appointed director of a laboratory for meteorological research, an office which he held until his death. This establishment was first located at Choisy le Roi, but in a few months it was moved to Parc St. Maur, to a locality rented by M. Renou. On the official establishment of the Bureau Central de Météorologie, M. Renou's station was selected as the central station for the climate of Paris, and the instruments were moved to a plot of ground which was assigned to the Bureau, and where they now remain. M. Renou has contributed to the *Annales* of the Bureau three important papers on the climate of Paris.

M. Renou deservedly received many honours, the principal being Legion of Honour, Chevalier (1847), Officier (1884), Officier de l'Académie (1873), and Officier de l'Instruction Publique (1891).

He died on April 6 at Parc St. Maur at the age of eighty-seven; and he has bequeathed his large library to the public library of his native place, Vendôme.

R. H. S.

NOTES.

THE first of the two annual soirees of the Royal Society will be held on May 14. This is the soiree to which gentlemen only are invited.

THE meeting of the Paris Academy of Sciences on April 14 was adjourned as a sign of respect for the late Prof. A. Cornu, whose untimely death was announced by the president in the following words:—"The Academy of Sciences has suffered a great loss. Prof. Cornu died on Friday, carried away rapidly by a disease which no one could foresee would terminate so sorrowfully. Our colleague was relatively young; he entered the École Polytechnique in 1860 and was nominated a mem-

ber of our Academy in 1878, at thirty-seven years of age. Esteemed as a professor at the École Polytechnique, and contributing to the Bureau des Longitudes every year notices written in perfect language, he died while in active scientific work, leaving saddened parents and friends behind him, and universal regret in the scientific world."

LORD KELVIN has met with an enthusiastic reception in New York, and the signs of profound regard which have been shown to him are expressions of a feeling shared by the whole civilised world. On Saturday he attended the ceremony of the installation of Prof. N. B. Butler, the new president of Columbia University, and when he appeared in the procession a student cried, "Hats off to Kelvin," and all the students, men and women, lifted their college caps. In an article upon Lord Kelvin's career, the New York *Sun* says:—"There are few instruments used on land or sea that do not owe something or everything to Lord Kelvin's active brain. His presence does honour to the United States of America. We welcome him heartily." The *Tribune* says:—"It is natural that many Americans, especially those engaged in scientific pursuits, should covet an opportunity of paying their respects to our distinguished visitor." Similar sentiments appear in other journals, all testifying to Lord Kelvin's greatness of mind and character. A booklet by Mr. John Munro, just published by Mr. H. J. Drane in a series of "Bijou Biographies" (No. ix.), contains many interesting anecdotes and incidents connected with Lord Kelvin's remarkable career, and is well worth reading by those unfamiliar with his life and work.

ON Monday a brilliant reception in honour of Lord Kelvin was given at the Columbia University by the American Institute of Electrical Engineers, the National Academy of Sciences, and other leading scientific associations. Mr. Elihu Thomson, president of the Houston-Thomson Electrical Company, Prof. F. B. Crocker, Prof. Butler, president of the Columbia University, and Prof. R. S. Woodward all delivered addresses in honour of the achievements of Lord Kelvin. The New York correspondent of the *Times* reports that when Lord Kelvin rose to reply the whole audience rose and cheered him enthusiastically for several minutes. He thanked the speakers for their kindly reference to himself in connection with the laying of the Atlantic cable, "but," he added, "Americans must never forget, as the world will never forget, the name of that great American, Cyrus Field. Science has advanced greatly during the years along all lines. One of its greatest achievements has been made by Signor Marconi with wireless telegraphy. It is a great achievement to have sent a message inland from several hundred miles out at sea in this way, and it indicates that the time will come when messages will be sped right over the ocean without the use of any intervening wire. But still, submarine telegraphy will continue to serve us well, even with wireless telegraphy established as a commercial success." Lord Kelvin then proceeded to review modern scientific events, and paid a high tribute to the work done by Mr. Edison in the field of electric lighting. Mr. Edison, who was amongst those present, rose and bowed his acknowledgments to Lord Kelvin, the audience cheering him heartily. Lord Kelvin concluded his speech with a reference to the invention which made possible the transmission of power at a high voltage, and the "harnessing of Niagara Falls." He predicted that a power plant would be established at Niagara that would transmit 40,000 volts a distance of 300 miles. When Lord Kelvin resumed his seat the applause was prolonged for several minutes. After that hundreds of the distinguished audience filed past and shook hands with Lord and Lady Kelvin.

AT the Royal Institution on Thursday, May 1, Dr. A. Smith Woodward will deliver the first of three lectures on "Recent Geological Discoveries." The Friday evening discourse on May 2 will be delivered by Mr. A. E. Tutton, on "Experimental Researches on the Constitution of Crystals"; and on May 9 by Prof. J. Norman Collie, his subject being "Exploration and Climbing in the Canadian Rocky Mountains."

THE Easter vacation party at the Port Erin Biological Station has suffered by the absence abroad of Prof. Herdman and Mr. I. C. Thompson, so that it was not possible to arrange any steam dredging expeditions. Nevertheless, much good work has been done on the shore and with the tow-net, and several workers have spent a profitable vacation at the station. These include Dr. Darbishire, Miss Pratt and Miss Drey from Owens College, Messrs. Pearson and Tattersall from University College, Liverpool, and Mr. Laurie from Oxford. Mr. Cole was to have conducted a vacation class, but was unable to cross owing to a family bereavement. The new and greatly improved station is progressing rapidly and will be opened in the summer.

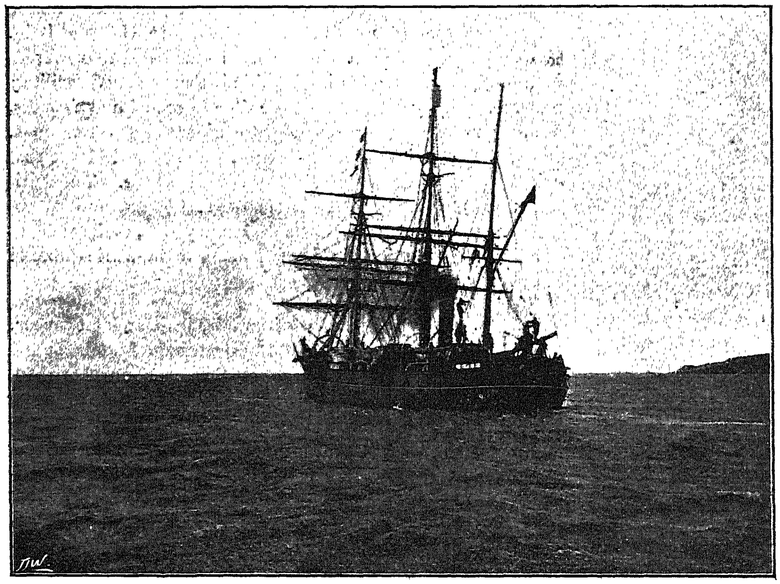
THE Decimal Association has just published a pamphlet containing strong expressions of opinion received from many Members of Parliament in favour of the compulsory adoption of the metric system of weights and measures in Great Britain. The chief reasons why a change from our present cumbrous system to a decimal system is desirable is that it would facilitate commerce, simplify calculation, save time in school and business, and bring us into closer touch with other civilised nations. Unless the system is made compulsory, there is little hope that it will be taught and used by the British people. The spirit which tolerates the present system of reckoning, and is indifferent to the advantages of the decimal system, is the same as that which regards scientific developments of industries abroad with unconcern.

THE text of the draft scheme of organised research on cancer, adopted by the Royal College of Physicians on March 24 and approved by the Royal College of Surgeons on April 10, has now been published. The scheme states that in order to promote investigations into all matters connected with, or bearing on, the causes, prevention and treatment of cancer and malignant disease, steps are to be taken, (1) to provide, extend, equip and maintain laboratories to be devoted exclusively to cancer research; (2) to encourage researches on the subject of cancer within the United Kingdom or in the British dominions beyond the seas; (3) to assist in the development of cancer-research departments in various hospitals and institutions approved by the executive committee; (4) and generally to provide means for systematic investigation in various other directions into the causes, prevention and treatment of cancer. Should the object of the fund be attained by the discovery of the cause and nature of cancer, and of an effective method of treatment, the Royal Colleges, with the consent of the trustees, are to be empowered to utilise the fund either (*a*) for equipping with the necessities for such treatment such hospitals as they may select, or (*b*) for forwarding research into other diseases. The fund is to be administered by a president, vice-presidents, trustees, honorary treasurer, general committee, and executive committee consisting of twelve members, one to be nominated by the Royal Society.

WE have received a reprint of the important paper by Col. G. E. Church, published in the March number of the *Geographical Journal*, on "Interoceanic Communication on the Western Continent." The paper first discusses possibilities of transcontinental railways in South America, but the main subject dealt with is the geographical conditions affecting the different

canal schemes in Central America. The probable traffic of a canal, when constructed, is analysed, and its chance in competition with North American railways estimated.

THE first place in the April number of the *Geographical Journal* is given to a series of three papers on the voyage southward of the *Discovery*, by Dr. H. R. Mill, Mr. George Murray, and Sir Clements Markham. Dr. Mill describes the equipment and routine work on board in meteorology and oceanography, and gives an account of his week's voyage to Madeira. Mr. Murray's paper continues the voyage from Madeira to the Cape, but it is chiefly occupied with an interesting account of a landing expedition on South Trinidad, an oceanic islet the name of which is familiar to readers of the "Cruise of the *Falcon*." Sir Clements Markham describes, from reports which have been sent home, the experiences of the *Discovery* from the time of leaving Cape Town until her final departure from Lyttelton for the Antarctic. During the eastward voyage, the *Discovery* met with exceptionally heavy weather and acquitted herself well, showing that so far as sea-going qualities are concerned her design leaves nothing to be desired, while the constructional defects developed, and partly



The *Discovery*.

made good in dock at Lyttelton, are not such as to cause apprehension of any kind. The chief features of the voyage were an excursion to lat. 63° S. in long. 140° E.—with the double object of observing the change of magnetic force along the agonic line, and of giving the ship and her crew a first taste of the ice—and a visit to Macquarie Island, where valuable collections were made. In conclusion, Sir Clements Markham describes the arrangements in progress for sending out a relief ship next June. A Norwegian whaler, the *Morning*, of Tonsberg, has already been purchased, but more funds are urgently needed for her proper equipment and dispatch. The photograph we reproduce from the *Journal* shows the *Discovery's* departure from Lyttelton.

THE United States Weather Bureau has published a discussion of the oss of life in the United States by lightning (*Bulletin* No. 30). The inquiry was begun in 1890, and has therefore extended over eleven years. The number of persons killed during 1900 was 713; of this number 291 were killed in the open, 158 in houses and 57 under trees. In the same year, 973 persons were injured; of these 327 were in houses, 243 in the open and 29 under trees. During the eleven years 1890-1900, the average number of persons killed yearly was 377. The greatest mortality by lightning, considering both unit area and density of population, is in the Ohio Valley and the Middle Atlantic States; but if density of population only be considered, it is in the Upper Missouri Valley and middle Rocky Mountain region. The great majority of storms occur in the summer season, but winter thunderstorms are not infrequent in the Gulf States and occasionally extend eastward along the Atlantic coast to Massachusetts. The *Bulletin* has been prepared by Prof. A. J. Henry, and contains some useful rules to be observed during thunderstorms and on the treatment of persons struck by lightning, even though they may be apparently dead.

MESSRS. A. GALLENKAMP AND CO., the London agents of a well-known firm of opticians of Zürich, have lately introduced to our notice two very handy and effective little instruments for obtaining the dew-point and humidity of the atmosphere without the necessity of calculating the different hygrometric values by means of the usual tables. One of the instruments, Lambrecht's polymeter, so-called from its showing several conditions, is a combination of the thermometer and hair-hygrometer, each provided with two scales, showing temperature in Fahrenheit degrees, elastic force of vapour in millimetres (or weight of vapour in grammes), the relative humidity and "number of degree," or the difference between the dew-point and the temperature of the air. For showing the temperature of the dew-point independently (if desired) a neat little instrument is used, consisting of a drum, to which a thermometer and polished disc are attached; a small quantity of ether is introduced into the drum and brought into contact with the bulb of the thermometer by forcing air into the drum by a very simple contrivance; as soon as the deposition appears on the disc, the temperature of the dew-point is indicated by the thermometer. The chief feature of these instruments is their portability and the facility with which they can be used. Both instruments will be found valuable in connection with questions of health and in certain industries which are affected by moisture; also for the prediction of weather, so far as it depends on the same cause. For the latter purpose a series of rules has been compiled by Dr. A. Troska.

IT was remarked by Laplace that when a liquid is free to rise in a capillary tube there may be several positions of equilibrium if the section is not uniform, and, moreover, that from general dynamical grounds positions of stable and unstable equilibrium follow each other alternately. A fuller investigation of this problem is now given by Signor G. Morera in a note contributed to the *Atti dei Lincei*, xi. 6. The author obtains, from mathematical considerations, a curve the intersections of which with the meridian section of the tube determine the positions of equilibrium. If in ascending the curve passes from the outside to the inside of the tube, the corresponding position of equilibrium is stable; if the contrary is the case, the position is unstable. Of course an exceptional case of what is sometimes called "stable-unstable" equilibrium occurs when Signor Morera's curve touches the meridian section of the tube. In the investigation it is assumed that the interior surface of the tube is a figure

of revolution about a vertical axis. The interest of the paper centres round the determination of the curve from which the positions of equilibrium are found.

The properties of focal lines have always presented a certain difficulty to the student of geometrical optics. In 1844, Sturm enunciated the theorem that all the rays constituting a small pencil emanating from a luminous point will, after any number of refractions, pass through two focal lines which are at right-angles to each other and to the middle ray of the pencil. Now if the refracting surfaces are surfaces of revolution on a common axis on which the luminous point is situated, the rays after any number of refractions will all intersect this axis, although it is not at right angles to the middle ray. On the contrary, if a screen be placed perpendicular to the middle ray at the point where it meets the axis of revolution, it is easy to see experimentally that the section of the pencil by this screen is approximately a figure of eight, not a straight line as Sturm's theorem would appear to indicate. We are glad to find that this point has been considered by M. H. Bouasse in a note contributed to the *Journal de Physique* for April, and his explanation should help to clear up the obscurities which exist in the conventional treatment of focal lines.

Our present state of civilisation has of necessity resulted in an annual increase in the amount of capital borrowed by man from the store of energy accumulated by our earth in bygone times, and the diversion of this capital to uses for which the world's annual income of solar energy was formerly deemed adequate. An instance of this tendency is afforded by the experiments of Dr. Selim Lemström, of Helsingfors, on the uses of electricity in stimulating the growth of cereals, vegetables and other plants. A German translation of Dr. Lemström's paper has now been issued by Dr. Otto Pringsheim. The investigation seems to have been suggested in the first instance by an attempt to connect the luxuriant growth of plants in high latitudes with the influence of electric currents associated with the Aurora Borealis. The experiments showed that for plants growing on arable land of medium quality an increase of 45 per cent. in the crops is obtainable; but the better the field is ploughed and cared for the greater will be the increase. On poor soil the effect is trifling. Certain plants, such as peas, cabbages and turnips, only lend themselves to electrical treatment after being watered. It is, however, injurious to most, if not all, plants to submit them to the influence of electricity in hot sunshine. In the introduction, Dr. Pringsheim makes some estimate of the cost of applying the method to agricultural purposes, and arrives at the conclusion that it can be made to pay. A further suggestion is that we have here an explanation of the needle-shaped leaves of coniferous plants which are well adapted to facilitate the passage of electricity, or, in common parlance, "attract electricity."

With the March number, the *Electro-Chemist and Metallurgist* starts its second volume in a new form. It is now issued as a magazine instead of, as hitherto, in the form of a weekly paper, and it must be admitted that its present style is much more suited to its contents and to the fact that it is only published bi-monthly. We wish the journal all success in its endeavour to concentrate attention on a branch of science in which this country is particularly behindhand. The present issue, amongst other interesting articles, contains an account, by Mr. J. R. Crawford, of the Crawford-Voelker electric lamp. This lamp has attracted considerable attention during the past few months, and one or two articles about it have appeared in the technical Press. There is, however, reason to believe that the problem of its commercial manufacture is not yet fully solved, but the experimental results are very promising. The filament, which is run in a vacuum, is composed of carbide of titanium, and is formed by baking in the arc a carbon filament which has been impregnated with an organic compound of titanium. An energy consumption of 2·5 watts per candle is claimed for a 200-volt lamp, which rises after 1000 hours' run to 3·35 watts per candle, the candle power falling in the same time from 16 to 13. This is a very much better result than can be obtained from a carbon lamp, and puts the Crawford-Voelker lamp almost on a level with the Nernst lamp. If the simplicity of the lamp, which requires no pre-heating, is taken into account, it will be seen that, for small units at any rate, it is likely to prove superior to Nernst's invention. In the interests of the electric light user it is to be hoped that the lamp will soon emerge from the laboratory stage of development.

The Society of Chemical Industry is gradually extending its borders, and in time, no doubt, will embrace all divisions of the English-speaking races. The New York Section, formed in 1900, is already equal to the London Section of the Society in numbers and importance, and Canadian and Australian Sections are now being formed. The first meeting of the Canadian Section was held on March 6, 1902, in Toronto, and was favoured with a paper by Mr. B. E. F. Rhodin upon the new electrolytic alkali works at Sault Sainte Marie, Ontario. These works were erected in 1900 to operate the Rhodin cell and process for production of alkali and chlorine by electrolysis, and a portion of the plant has been in use since early in 1901. The cell is of the non-diaphragm mercury type, and differs from the better-known Castner cell only in the mechanical means adopted for producing circulation of the sodium amalgam and of the mercury between the anodic and kathodic compartments of the cell. The Rhodin cell cannot be worked in this country owing to litigation, which is still pending, relating to the validity of the Rhodin patents, and the works in Canada represent the first industrial application of the cell and process. The Canadian Electro-Chemical Company are the owners of the works referred to, and a decomposing plant of 120 cells, equivalent to a daily production of 4½ tons caustic soda and 9 tons bleach, has been erected at Sault Sainte Marie. Three turbo-generators, each of 220 k.w., have been installed, and these are driven by water from the St. Mary's River, giving a head of 19 feet at the Power-house. The works are not yet in full operation, as the commercial conditions in Canada are not at present favourable for the sale of the maximum output. It is hoped by the promoters of this Company that at an early date the whole of the Canadian requirements of caustic soda and bleach, will be met by the production of the electrolytic process operated at Sault Sainte Marie.

We have received from Messrs. Friedlander, of Berlin, a copy of "Naturæ Novitates" for 1901, containing the usual valuable lists of zoological literature.

In the April number of the *Zoologist* a correspondent directs attention to the probable duration of life in the great white snail. A number of these were turned down at Blaxhall, Suffolk, in 1882 and again in 1884, and as they do not appear to have bred and some are still living, the inference is that the survivors cannot be less than eighteen years of age, while some are probably much older.

At the auction rooms of Mr. J. C. Stevens on Thursday last there was sold a portion of the collection of birds' eggs formed by the late Mr. Philip Crowley, and containing a fine series of British birds' nests with eggs, and also eggs from another property. The three lots of chief interest were a fine specimen of the Great Auk, 315*l.*; an egg of the Great Auk, 252*l.*; and a very fine specimen of the egg of the Great Æpyornis, slightly cracked, 42*l.*

A LARGE portion of part iii. and the whole of part iv. of the *Archives de Zoologie experimentale* for 1901 are occupied by an elaborate dissertation on the structure and function of the ciliated epithelium of animals—the result of experiments and investigations carried out by Monsieur P. Vignon during the last three years. The main result of the observations, according to the author, is to prove or confirm the existence of "biological coordination." In the same journal M. E. Topsent describes the sponges of the Algerian coast.

WE have received a copy of an interesting paper by Herr W. Voight, from the *Verhandlungen* of the Natural History Association of Prussian Rhineland, &c., describing the extermination of two species of annelids from the freshwaters of the district and their replacement by a third. It appears that until recently *Planaria alpina* inhabited the streams of the Hundsrückgebirge, in the north-western Thuringerwald, and *Polycelis cornuta* those of the Taunus. It is inferred that they have been inhabitants of these regions since the Glacial epoch. At first *P. alpina* alone inhabited both areas; in the Hundsrückgebirge it persisted, but in the Taunus its territory was invaded by *P. cornuta*, which became the dominant form. As the climate grew warmer, a third species, *Planaria gonocephala*, appeared in the lower past of the streams, and has since been gradually spreading upwards until it has replaced both the others over the greater part of their area, the disappearance of *P. alpina* from many streams in the one district and of *P. cornuta* from those of the other being recent events.

IT is but seldom that it falls to the lot of the same individual to reoccupy the presidential chair of a scientific (or any other) society after an interval of twenty-one years, and we have accordingly much pleasure in offering our congratulations to Prof. R. Meldola on his assumption of that position at the recent "coming-of-age" of the Essex Field Club. Indeed, the club is to be congratulated on the "staying powers" of its officials generally, the president remarking that, with a single exception, the whole of the office-bearers during its twenty-one years of existence are still among us. Probably this is absolutely unique. In his presidential address on the occasion referred to, which is fully reported in the April number of the *Essex Naturalist*, Prof. Meldola summarises the scientific work of the Society; and it is a record of which the Society may well be proud. In many respects Essex is a county offering peculiarly favourable opportunities for local scientific research. It has a large seaboard, in common with Suffolk, it contains deposits of "Red Clay," the brick-earths of Ilford and elsewhere teem with remains of Pleistocene mammals, and prehistoric and other ancient works of man abound within its limits. Moreover, in Epping Forest it possesses a tract full of interest alike to the naturalist and the antiquarian. To the workers in all the branches of local scientific research the president does full justice.

IN the *Jahrbuch der k.-k. geol. Reichsanstalt*, Band li., Heft 1 (1901), Dr. O. Abel contributes a very interesting paper on some curiously marked pebbles from the Algerian Sahara. The pebbles, as the result of exposure to desert erosion, possess a characteristic surface sculpture of ridges and furrows, which have a more or less regular radial disposition. The special interest of this character lies in its wonderfully close resemblance to the sculpture frequently exhibited by moldavite, made more particularly familiar to us through Dr. F. E. Suess's advocacy of the meteoric origin of this mineral. The sculptured pebbles dealt with in this paper are of discoid form, and radial furrows are impressed on both sides of the disc. At the periphery the furrows become more plainly marked, and tend to pass across the margin of the disc in a direction at right angles to the flattened surfaces. The author examines the possible causes of this curious sculpture, and concludes that the ordinary action of the wind, driving sand-grains against the motionless pebbles, would be quite inadequate to produce the stellate figures on opposite surfaces of the stone. He believes, however, that the natural sand-blast is, in fact, the true eroding agent, but that the pebbles were rotating when attacked by it, while raised from the ground and driven forward over the surface of the desert during repeated sand-storms. That the stellate sculpture would result from such agencies the author considers to be proved by certain experiments carried out by Dr. F. E. Suess, to which he refers. As regards the analogous sculpture of moldavite, the author suggests that it might also have been produced by the prolonged exposure of the moldavite fragments to desert conditions, an idea which is supported by the form and size of the moldavite specimens, as well as by the relative softness of this glass when compared with quartz sand. At the same time, he considers that the theory of the cosmic origin of moldavite is in no way weakened by such a conclusion. The paper is excellently illustrated.

THE University of Texas Mineral Survey, under the direction of Mr. W. B. Phillips, has issued a report on sulphur, oil and quicksilver in Trans-Pecos (*Bulletin*, No. 2, 1902). In the Cretaceous area in Texas both heavy and illuminating oils are found at no great distance from each other. The subject was dealt with in *Bulletin* No. 1; some further particulars are now given, and complete analyses of all the coals, lignites and asphalt rocks, together with tests of the fuel value of the different oils, are in preparation. Quicksilver ores, chiefly cinnabar, occur in Brewster county in hard Cretaceous limestone and in decomposed shale, the rich stringers and pockets of cinnabar being found along bedding-planes and in cracks of the limestone associated with shaly matter. Intrusions of dolerite occur near by, and with them are probably connected the disturbance of the strata and the deposition, most likely from aqueous solution, of the metallic impregnations. Important sulphur deposits are met with in El Pasco county, and it is considered that 300,000 tons are available within forty feet of the surface in the vicinity of Maverick Springs. The area is described as consisting of a white plain of gypsum with a few small hills upon it, those on the west of gypsum, and those on the east of more recent conglomerate and white dolomite. The beds of gypsum overlie Upper Carboniferous sandstones and shales and are probably of Permian age. Throughout the tract sulphur springs are common, sulphur occurs in various forms, and the soil in places contains as much as 5 per cent. of free sulphuric acid. The gypsum beds are from 300 to 500 feet thick, and sulphur occurs in small crystals embedded in white gypsum, sometimes to the extent of 25 per cent. Elsewhere the sulphur occurs as a bluish ore in a siliceous earthy gangue, yielding 70 per cent. of sulphur. The matrix is locally bituminous, and it is noted that in all localities there are signs of oil. From a careful study of the subject, Mr. E. M. Skeats is of opinion that the richer bluish ores were formed from sulphur waters at a time when they were above ground, and probably through the agency of certain algæ which are plentiful in the sulphur springs to-day. All the sulphur occurs in and with gypsum and in connection with water containing sulphuretted hydrogen. The ores in which the sulphur occurs as crystals were probably formed by the decomposition of sulphuretted hydrogen given off from the highly charged water when it entered a porous or broken stratum. It is further considered that the gypsum may have been at one time carbonate of lime, for in many places it is difficult to say where limestone ends and gypsum begins.

WHILE we have large engineering workshops all over the country supplying machinery for practical use, it is with interest we note that a journal dealing with model making on a very

practical scale is published for the benefit of young engineers and amateurs. The *Model Engineer and Amateur Electrician* forms the medium for enthusiastic students fond of engineering, and we find in its columns practical working drawings and photographs contributed and explained in a very lucid manner. Under the heading of "Queries and Replies," readers in difficulty for information get their wants adequately supplied in a subsequent issue. A good example of this is found on p. 165 (April number), where a working general arrangement of a model locomotive is given for a two and a half-inch gauge railway and drawn to a scale of half inch to a foot, in the design of which we notice water tubes placed inside and across the firebox, an idea only introduced into actual locomotive practice a few months ago. Electricity and petrol motors also form an important part within the columns of the periodical, practical types of dynamos, motors, &c., being thoroughly dealt with. A paper of this description brings within the scope of students a practical application of science to mechanical engineering, enabling them to grasp the fundamental ideas of construction and also to carry them through into a practical working form.

IN the article by Sir Michael Foster, on the Regina Margherita Observatory, in last week's NATURE (p. 569), the height of the Gnifetti hut, given as 4560 feet, should be 4560 metres; the height in feet is 14,961.

SEVEN volumes belonging to the valuable "Scientia" series have been received from the publisher, M. C. Naud, of Paris. Six of the volumes (Nos. 13–18) are in the physical section of the series, and one (No. 12) is in the biological section. Each volume may be described as a short review of knowledge of the subject with which it deals, or a statement of observations and results interpreted in the light of recent scientific thought. The titles and authors of the volumes which have just come to hand are "Cryoscopie," by the late M. F. M. Raoult; "Franges d'interférence," by Prof. J. M. de Lépinay; "La Géométrie non-euclidienne," by M. P. Barbarin; "Le Phénomène de Kerr et les Phénomènes électro-optiques," by M. E. Néculcéa; "Théorie de la Lune," by Prof. H. Andoyer; "Géométrographie, ou Art des Constructions géométriques," by M. E. Lemoine; and "L'Hérédité acquise: ses conséquences horticoles, agricoles, et medicales," by M. M. J. Constantin.

THE additions to the Zoological Society's Gardens during the past week include a Campbell's Monkey (*Cercopithecus campbelli*), a Hocheur Monkey (*Cercopithecus nictitans*) from West Africa, presented by Captain Joseph C. Verey; a Sooty Mangabey (*Cercocebus fuliginosus*) from West Africa, a Black-headed Lemur (*Lemur brunneus*), a Red-fronted Lemur (*Lemur rufifrons*) from Madagascar, two King Penguins (*Aptenodytes pennanti*), a Thick-billed Penguin (*Eudyptes pachyrhynchus*) from the Macquarie Islands, two Common Rheas (*Rhea americana*) from the Argentine Republic, a Raven (*Corvus corax*) European, two Eupatorian Parrakeets (*Palaeornis eupatria*), three Indian Rat Snakes (*Zamenis mucosa*), five Tigrine Frogs (*Rana tigrina*) from India, deposited.

OUR ASTRONOMICAL COLUMN.

ASTRONOMICAL OCCURRENCES IN MAY.

May 1. 1h. Jupiter in conjunction with moon. Jupiter 5° 59′ S.
1. 13h. 12m. to 14h. 7m. Moon occults c' Capricornii (mag. 5·2).
4. 5h. Venus in conjunction with moon. Venus 4° 19′ S.
7. Sun partially eclipsed, invisible at Greenwich.
14. 12h. 9m. Minimum of Algol (β Persei).
15. Venus. Illuminated portion of disc = 0·589, of Mars = 0·996.
17. 8h. 58m. Minimum of Algol (β Persei).

May 20. Saturn. Outer minor axis of outer ring = 14″·84.
20. 13h. 18m. Moon makes a near approach to α Libræ (mag. 3).
26. 20h. Saturn in conjunction with moon. Saturn 5° 18′ S.
28. 6h. Mercury at greatest elongation, 23° 3′ E.
28. 12h. Jupiter in conjunction with moon, Jupiter 5° 57′ S.
29. 4h. Mercury in conjunction with Neptune. Mercury 2° 52′ N.

COMET 1902 *a* (BROOKS).—The discovery of the first new comet of the present year was made by Mr. Brooks at Geneva on April 15, and the following data are supplied for the position at discovery and various subsequent epochs:—

1902.	h. m.	Place.	R.A. ° ′ ″	N.P.D. ° ′ ″	Observer
April 15	16 0	Geneva	347 2 0	62 35 0	Brooks.
,, 16	14 37	Kœnigsberg	348 55 16	63 53 25	—
,, 16	15 8·1	Copenhagen	349 3 12	63 58 39	Pechüle.
,, 16	15 30·2	Bamberg	349 6 54	64 1 1	Hartwig.
,, 16	15 45·6	Lick	350 16 56	64 47 34	Aitken.

The original announcement of discovery described the comet as being bright, with a tail. A later description by Prof. Hartwig states that the comet is about 8·5 magnitude, circular in form with a diameter of 3′. There is a central condensation and a tail somewhat less than 30′ in length.

At discovery the new comet was quite close to β Pegasi; it is now moving to the south-east rather rapidly.

NEBULÆ AND THEIR VELOCITIES IN THE LINE OF SIGHT.—Dr. J. Hartmann, of the Potsdam Observatory, gives (*Sitzungsberichte der Kön. Preuss. Akad. der Wissenschaften zu Berlin*, February 27, 1902) an interesting account of his investigation to determine the velocities in the line of sight of several gaseous nebulæ, the spectra of which he has photographed. The work was suggested to him after he had secured a very strong image of the planetary nebula G.C. 4390 with the Potsdam photographic refractor of 80 cm. in the short time of exposure of 15 minutes. In the investigation two spectroscopes were employed, that which he designates apparatus I. consisting of a flint glass prism of 60°, a collimator of 530 mm. and a camera of 720 mm. focal lengths; while apparatus III. has three flint glass prisms of 63°, a collimator of 480 mm. and a camera of 410 mm. focal lengths. The exposures of the different negatives obtained varied from 90 to 270 minutes, and the comparison spectrum photographed in each case was that of the arc spectrum of iron; the nebulæ photographed and the spectra of which were examined for movement in the line of sight were G.C. 4390, 4373, and N.G.C. 7027. Dr. Hartmann determined first of all the velocity of the nebula G.C. 4390 from the measurements of the hydrogen lines Hβ and Hγ, and from this value deduced the wave-lengths of the two chief nebula lines. All the values for the velocity as determined from the different negatives agreed well among themselves, and the deduced mean values for the wave-lengths of the two nebula lines were 5007·04 and 4959·17. While the former value is practically identical with the wave-length obtained by Prof. Keeler for the Orion nebula 5007·05 ± 0·03, the latter is somewhat greater than Keeler's value, namely 4959·02 ± 0·04. Dr. Hartmann finds that the discrepancy is easily explained, as Keeler used a spark spectrum of iron for comparison, and the two lines of iron close together at this wave-length behave differently under the two electrical conditions (arc and spark). If it be assumed that Keeler's comparison line was that at wave-length 4957·78 instead of at 4957·63—and Dr. Hartmann seems to have good reasons for making this assumption—then his own result is brought in complete accord. The paper further gives details of each of the measurements on the different photographic negatives employed, but the following table shows only the mean results obtained, giving Keeler's values for comparison:—

Nebula		Velocity Hartmann km.	Keeler km.
G.C. 4390	...	−10·5	−9·7
G.C. 4373	...	−65·8	−64·7
N.G.C. 7027	...	+4·9	+10·1

It is interesting to note that Dr. Hartmann finds slightly different values of the velocity for the middles in relation to the

edges of the nebulæ; and the curved and inclined nature of the lines, when compared with those in the comparison spectra, indicate still more clearly relative movements in the nebulæ themselves.

THE RED SPOT ON JUPITER.—In the *Astronomische Nachrichten* (Bd. 158, No. 3786), Mr. A. Stanley Williams gives a discussion of his observations of the red spot on Jupiter during 1901. The planet was badly placed owing to its great southerly declination, but during the summer months the definition was exceptionally good. Tables are given of the times occupied in the transit of the spot over the mean meridian of the disc, measures being taken from both the middle and following end of the marking. The mean rotation period thus determined is 9h. 55m. 40·92s., which is 1·38s. shorter than the value deduced from the observations of the previous year. This shortening of the length of the rotation period has also been noted by several other observers. In appearance the spot was very faint, especially at the preceding end. The following extremity, however, was fairly dark; a distinct though faint reddish tinge was generally noticeable.

Several reductions of measures of the length of the spot are given as evidence in favour of Prof. G. W. Hough's statement that the spot has not materially changed in size during the last twenty years.

THE MEANING OF THE WHITE UNDER SIDES OF ANIMALS.

PROF. E. B. POULTON has sent us the following account of a discovery of great interest to naturalists made by Mr. A. H. Thayer, and a paper in which Mr. Thayer himself describes his observations and conclusions. This paper has been specially revised for publication in NATURE, and with Prof. Poulton's introduction will be welcomed by many observers of nature.

No discovery in the wide field of animal coloration has been received with greater interest than Mr. Abbott H. Thayer's demonstration, by means of models presented to the Natural History Museums of London, Oxford and Cambridge, of the cryptic effect of the gradation of animal tints, from dark on the back to white on the belly. In spite of the intense interest aroused in students of animal life from the side of art as well as from the side of zoological science, the underlying principles have been frequently misunderstood.

Mr. Thayer has seen some of the accounts of his discovery which have appeared in this country, and he feels that the explanation offered has been inadequate and sometimes misleading. He has therefore sent for publication in NATURE a further statement, which may be regarded as an appendix to his original memoirs in *The Auk* for April and October, 1896. In this statement he makes a too generous acknowledgment of my partial discovery of the same principle (unknown to him in 1896) in two isolated cases in 1886 and 1887. I should wish, therefore, to state that I did not discover, and could never have discovered, what it required the eye of an artist to see—viz. the manner in which the total colour-effect of the cold white under side of an animal bathed in shadow and yellow earth reflections matches exactly its earth-brown back bathed in the cold blue-white of the sky. I furthermore failed to see the wide application of that part of the principle which I did discover, and not only failed to see it, but actually applied to the white under sides of animals and the white eggs of certain birds the erroneous interpretation which was then commonly received, the interpretation which Mr. Thayer disposes of so completely in the article printed below.

The following account was drawn up by the present writer for the models presented by Mr. Thayer to the Oxford University Museum. It is believed that the description of the principles concerned may be useful to students in other museums. I should add that Mr. Thayer cordially approves this description of the principles he has discovered:—

"Models to show the manner in which wild animals are commonly hidden.

"Made and presented by Abbott H. Thayer, Esq., of Scarbro, N.Y., U.S.A.

"If the two model ducks in this case be looked at from a little distance, the left-hand model will appear almost invisible, transparent and ghost-like, while the right-hand one stands out in startling contrast. The former has a colour arrangement similar to that commonly found among wild animals in nature, while the latter is entirely different.

"There are two quite distinct elements in the concealment of the left-hand model, and of such an animal as a hare or a woodcock. First there is loss of all appearance of *solidity*, secondly there is the harmony with the *colour* of the background.

"We are led to believe that any small object is *solid* and possesses a definite shape solely because of the varying depth of shade on parts of its surface more or less shielded from light. (In the case of a very large object, such as a mountain, the adjustment required when the eye focusses its near and distant parts may also aid the judgment, but this could not apply to anything so small as an animal). Thus an artist can make an object on the flat surface of his canvas appear to stand out as a solid because he paints the shadows as they would be caused by the varying degree of light on the surface of a solid. Mr. Thayer has shown for the first time that the opposite operation is quite possible, viz. that an artist can paint a solid object so as to obliterate the shadows and as a result to remove all appearance of solidity. In the case of an object illuminated, as animals are in nature, by the direct and reflected light of the sky, this is achieved by colouring the object darkest on the top where the light is strongest, gradually less dark on the sides where the light progressively lessens, and white underneath where the light is least, the darkening of the colour corresponding exactly to the strengthening of the illumination. This will be seen at once by turning the handle at the side of the case. The right-hand model is, on the other hand, of uniform colour, and appears far darker on the sides than the back, and darker still, almost dead black, underneath.

"In fact the model which is the same shade of colour all over appears to be a different shade everywhere because of the difference in illumination; while the model which is of a different shade at every level appears to be the same shade all over because the differences of shade exactly counterbalance the differences of illumination.

"Animals in nature are commonly graded in colour like the left-hand model; and Mr. Thayer's discovery of this great and yet simple principle was made because he, as an artist, recognised the ghost-like appearance of wild animals and then set to work to analyse its cause.

"But the obliteration of solidity would not effectually conceal if the *colour* did not harmonise with the environment. The back of the model, and of animals generally, is of the same tint as the brown of the earth bathed in the cold blue-white light of the sky; the under side of the model and the belly of animals is of a cold blue-white bathed in shadow and yellow earth reflections. These two mixtures produce colour effects which are similar to each other and to the mixtures of intermediate components on the sides.

"Hence with *solidity* eliminated and with *colour harmony* between environment and object, the latter appears to be but a part of the former. It is thus possible to explain the concealment of the left-hand model, or of such an animal as the hare crouching motionless on bare earth, or the numerous sand-coloured quadrupeds, birds and reptiles of the desert; but upon the surface of most animals markings are added which suggest the details of a more varied environment, such as that presented by masses of brown leaves, twigs, reeds, grasses, lichen, &c. It is obvious that in an environment full of varied detail a colouring producing a uniform effect would not conceal; hence the markings on the woodcock, ptarmigan, &c. In such cases the animal itself appears to become part of the background while its markings are seen as the details.

"Mr. Thayer has also gained further proof of the accuracy of his interpretation by painting out the gradation of colour on the sides and belly of a stuffed bird, thus extending the colour of the back over all parts of the surface. Although a living bird with its natural colouring would be almost invisible in nature, the painted specimen became extremely conspicuous when placed in the natural attitude and amid natural surroundings.

"It is not too much to assert that the broad fact of the colour gradation on the sides of animals passing into white underneath has now for the first time received its interpretation. "EDWARD B. POULTON.

"Oxford, January 22, 1902."

THE LAW WHICH UNDERLIES PROTECTIVE COLORATION.

I desire at the outset to point out that my demonstration of the principle of Protective Coloration is not the demonstration of a *theory*, but of an indisputable fact, namely, that if an object be coloured so that its tones constitute a gradation of shading and of colouring counter to the gradation of shading and of colouring which light thrown upon it would produce, such object will appear perfectly flat, retaining its length and breadth, but having lost its appearance of thickness, and when seen against a background of colour and pattern similar to its own will be essentially indistinguishable at a short distance. All persons who have seen the models which illustrate this fact know that they prove it.

Now, if this stands proved, *the fact that a vast majority of the whole Animal Kingdom wear this gradation, developed to an exquisitely minute degree, and are famous for being hard to see in their homes speaks for itself.* It is plain that their colour-gradation can no more escape effacing their look of solidity than the Law of Gravitation can escape drawing a projectile to the earth.

This is so obvious that one hears on all sides expressions of wonder that it was so long unnoticed. I may add that all persons of trained sight, such as artists, perceive it everywhere among wild creatures. Other people supplement their undeveloped sight sense by their other senses, and if they *know* the animal is solid think he *looks* solid. But the time will come when even at zoological gardens, where animals are more or less abnormally environed, people will find a new charm in recognising everywhere this wonderful adjustment of their colouring, and in perceiving its effect.

Let anyone look at a ball, or egg-shaped object, placed anywhere out of doors, and when he has recognised its shading from its light side to its dark, try to so colour it, where it stands, as to obliterate both its shading and its colour-gradation. (The sky-lit side is commonly the bluer). If he succeed, he will find that Nature has swiftly guided him through the same process which has taken her so long on the coats of animals, and that he has given the object the counter-gradation I speak of, and it will have dawned on him that so long as light makes its *one* gradation on objects, there is only the *one* way to neutralise it. In short, I simply prove that this arrangement of animals' colours is what so marvellously effaces them, and leave it to others to discuss the question whether concealment be a benefit to an animal and whether the fact that it is a benefit be the cause of his being concealed.

All who believe in Natural Selection will, of course, feel that this colour law is its work, and since it is so almost universally in use, and accounts, apparently, so almost exhaustively, for all the attributes of graded animal colouring, I believe it will ultimately be recognised as the most wonderful form of Darwin's great Law.

It stands alone in the startling attribute of being the only known or so far conceivable device for making objects in *full light not appear to exist.* This is a distinct plane above even the great beauty of Protective Resemblance, where the deception is of a more material nature, one thing passing itself off for another *thing.* The beautiful sequence of this law, which causes the grading colours to become a picture of the background, I will not force upon those who have not yet digested the first part.

It might be worth pointing out that the old theory that the bellies of fish and tree birds were white to match the sky when seen from below finds itself essentially done away with, since the fishes' or birds' opacity causes even their white to look very dark against an ordinary sky, while this same white proves to work so brilliant a success for the purpose I have shown. All people know the ghostly transparent look of fish in the water. The white bellies of birds do help them to match the *translucent foliage overhead* when seen from below, but the cold sky-holes between the leaves are far too bright. Natural Selection has, of course, surely modified all attributes to suit, not merely main ends, but all minor ones, according to the rank of their importance.

Since publishing my papers in *The Auk* for April and October, 1896, I find that Prof. Poulton perceived years before their appearance the power of a countergrading of light to make the round surface of a pupa appear flat, and in another case the power of light colour in a depression to make the concavity disappear. In both of these cases he perceived the very *Law of Light and Shade* on which the Fact of Protective Coloration rests, and recognised the Fact itself in these instances. In his "Notes in 1886 upon Lepidopterous Larvæ, &c.," read April 6, 1887, he says (*Trans.* Ent. Soc. Lond., 1887, p. 294), "Although the cleft [between the posterior part of the body of the larva of *Rumia crataegata* and the branch] is largely filled up, . . . a considerable furrow remains, but this is not apparent because of the light colour of the fleshy processes, which prevent the attention from being directed to the shadow which would otherwise indicate the position of the groove. The processes, therefore, attain the object of softening the contact between the larva and its food-plant in a two-fold manner, by partially filling up the cleft and by neutralising the shadow in the groove which remains. I have also noticed the processes in the larva of *A. betularia*, and I believe that they are of very general occurrence in *Geometrae.*"

His other case is to be found in his "Notes in 1887 upon Lepidopterous Larvæ, &c.," read October 3, 1888. He says (*Trans.* Ent. Soc. Lond., pp. 595–6), "The most extraordinary thing about this resemblance [of the pupa of *Apatura iris* to a sallow-leaf] was the leaf-like impression of *flatness* conveyed by a pupa which was in reality very far from flat. Thus the length of the pupa was 30·5 mm.; the greatest breadth (dorso-ventral diameter), 11·5 mm.; the greatest thickness (from side to side), 8·5 mm. . . . But exactly in these places, where the obvious thickness would destroy the resemblance to a leaf, the whole effect of the roundness is neutralised by the increasing lightness of these parts—a lightness which is so disposed as to just compensate for the shadow by which alone we judge of the roundness of small objects. (Much larger objects can be judged of by the change of focus, which becomes necessary as their near or distant parts are observed.) In shading the drawing of an object so as to represent roundness, the shade is made to become gradually less and less deep as the tangential planes represented come nearer and nearer to a right angle with the axis of vision. So here, the converse of shading—the whiteness neutralising the shadow which shading is intended to represent—dies off gradually as the [representation of the] mid-rib is approached.

"The whiteness is produced by the relative abundance of white dots and a fine white marking of the surface which is present everywhere, mingled with the green. The effect is, in fact, produced by a process exactly analogous to stippling.

"By this beautiful and simple method a pupa, which is 8·5 mm. from side to side in its thickest part, appears flat and offers the most remarkable resemblance to a leaf which is a small fraction of 1 mm. in thickness." ABBOTT H. THAYER.

Scarbro, New York.

REPORT OF THE SMITHSONIAN INSTITUTION.

DR. S. P. LANGLEY'S report upon the operations of the Smithsonian Institution for the year ending last June has just reached this country. Many subjects of interest are referred to in the report, but we are only able to mention a few, which will, however, be sufficient to show that the Institution is taking a foremost part in the advancement and diffusion of knowledge among men of all civilised nations.

Hodgkins Fund.—Among the many applications for grants from the Hodgkins fund, it has been found practicable to approve several which conform to the conditions of the bequest. Prof. Wallace C. Sabine, of Harvard University, has received a grant for the aid of his investigations on sound, the particular phase of the problem under investigation being the subject of loudness and interference. This research requires apparatus of special design, part of which is now complete and is satisfactory. Prof. Sabine, who had charge of the design of the new symphony hall in Boston, has for several years given much attention to the problem of architectural acoustics, or the science of sound as applied to buildings. It is expected that his complete report will be of much practical interest in connection with this subject.

Details of the progress of the research mentioned in the last report as conducted by Dr. Victor Schumann, of Leipzig, have been received. The most noteworthy points in the results so far refer, perhaps, to the relation of light and electricity and to the probable insight into the nature of the Röntgen rays to be gained in the course of this investigation.

The investigations of Dr. von Lendenfeld, of the University

of Prague, are still in progress, and it is anticipated that his final report, which is now awaited, may furnish data available for greatly improving the construction of the meteorological kites now in constant use, and thus be the means of adding materially to our knowledge of atmospheric conditions at high altitudes, the practical application of which is of such general interest and usefulness.

The interesting experiments in connection with kites and with air currents at varying altitudes, which have been prosecuted for some time at the Blue Hill Meteorological Observatory by Mr. A. Lawrence Rotch, are still in progress, an additional grant having been approved this year on behalf of Mr. Rotch. It will be remembered that the original grant mentioned was made for the purpose of securing automatic kite records at a height of more than 10,000 feet, an altitude which so lately as four years ago had never been attained. Successive grants have since been made, and the persistence and skill of Mr. Rotch and his assistants have enabled him to surpass his own extraordinary record of 14,000 feet.

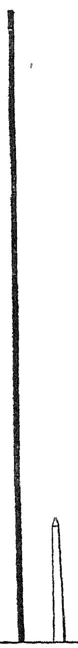


FIG. 1.—Diagram illustrating height of packing boxes, resting one upon another, used in transmitting exchanges from the United States to foreign countries during the fiscal year ending June 30, 1901, as compared with the height of the Washington Monument. Height of monument, 555 feet; height of boxes, 2,775 feet.

Dr. Carl Barus, of Brown University, has completed his research on ionised air, and his report is now in course of publication in the Smithsonian Contributions to Knowledge. This research on atmospheric conditions, in investigating the production of nuclei, determining their number per cubic centimetre, their velocity, their association with ionisation, the effect of the presence of the electric field, &c., proves interesting, not only in its own methods and results, but because of its agreement with the data obtained by other investigators from different experiments and theoretically different points of view.

The research of Prof. Louis Bevier, of Rutgers College, in connection with the analysis of vowel sounds, is steadily progressing. During the year detailed studies of several vowel sounds have been made with results which agree well with the conclusions arrived at through an entirely different method by von Helmholtz in his analysis of German vowels. The lower resonance detected in our vowel sounds by Dr. Bevier, and not recorded by von Helmholtz save for "*a*," will later be the subject of detailed discussion which will endeavour to establish and explain these facts.

Dr. Marey, of the French Institute, has received a grant in aid of his experiments on air currents. This research has been materially furthered by the successful application of chrono-photography, a field in which Dr. Marey's experiments have heretofore been noteworthy. By this means it has not only been possible to analyse the movements of waves and currents of liquids which are invisible to the naked eye, but even the displacements of molecules. From reports so far submitted, but as yet necessarily incomplete, it is believed that this research will aid materially in the solution of various problems connected with the mechanics of propulsion in fluids, at the same time rendering service in solving practical questions of ventilation, &c. The reader, if he has not noticed the rare experiment of successful machine flight of heavy bodies through the air, has probably had his attention called at times to the extraordinary difference between the performance of small steam vessels like yachts or tugs, where with equal power one glides through the water almost as though it offered no resistance, while another labours in rolling a formidable wave before it. The same differences occur in still more subtle form in the air. We cannot with the naked eye see separately, in either case, the currents that produce the effect, but by Dr. Marey's ingenious experiments photographic records can be obtained from which the forms which offer the least resistance can be studied.

The experiments of Prof. A. G. Webster, of Clark University, on the propagation, reflection and diffraction of sound, have achieved a result of practical value in the construction of an instrument capable of emitting an accurately measured sound. It is thus possible, in treating persons of defective hearing, to decide with exactness as to the degree of deafness in a subject, and to say if the power of hearing varies at different times. An instrument which furnishes the means of accurately determining these points should prove of value in medical treatment.

Prof. William Hallock, of Columbia University, New York, is conducting a research on the motion of a particle of air under the influence of articulate sound. General investigations allied to this subject, which are carried on in the laboratory of Columbia University, although in no way aided by the Hodgkins fund, have contributed helpfully to a knowledge of the principles underlying these experiments, and especially to certain parts of the investigation referring to the relation between the amplitude of vibration of an air particle and the amplitude of vibration of a film, or dust particle, suspended in the air. Dr. Hallock's research will be continued during the present year, when a final report is expected.

International Exchanges.—The importance of the work accomplished by the International Exchange Service is now well understood among men of science, and the benefits derived from it in the interchange of the publications of the civilised world are appreciated. The liberality of the American people in gratuitously supplying their scientific literature to appreciative students of it, wherever they may be, and the provision for its transmission at the expense of the United States Government and of the Smithsonian Institution jointly, are highly valued in the scientific world.

The term "International Exchanges" is now applied to the mutual exchange between Smithsonian correspondents everywhere of printed books on subjects of interest to the student in any branch of human knowledge.

The field covered by correspondents of the Smithsonian Institution and the contributors and recipients of its exchanges is now represented by one hundred and forty-eight countries, covering every part of the civilised world and extending to several countries where enlightenment has only commenced to manifest itself. In the latter are some of the most appreciative correspondents of the service. Outside the United States the Smithsonian correspondents now number 27,556, and including the United States there is a grand total of 35,705, an aggregate increase of 1754 during the year. The parcels received for transmission in 1900 numbered 121,060 (many of which contained several separate publications), representing an increase over the previous year of 7497 (Fig. 1).

In his last report Dr. Langley presented an account of his visit to London and Berlin during the summer of 1900 for the purpose of impressing upon the British and German Governments the desire of the Institution that they should each establish an international exchange bureau, or at least arrange for the transmission and distribution of exchanges so far as the United States is concerned. This work has been carried on between the United States and Germany and Great Britain from the beginning at the expense of the Institution, which has paid all expenses, even to the employing of a salaried agent in both countries. As yet no definite action has been taken by either Government.

Astrophysical Observatory.—It will be remembered that the observations of last year's eclipse by the Smithsonian expedition raised interesting questions as to the existence of intramercurial planets and as to the nature of the coronal radiations. So far did the interest in these problems extend that it was thought worth while to send an expedition from the Astrophysical Observatory to Sumatra to observe the total eclipse of May 18, 1901, and to repeat and extend the bolometric observations on the coronal radiation and the photographic observations for possible intramercurial planets. Solok, Sumatra, was the point selected for the observations. But, unfortunately, at the time of the eclipse the whole sky, excepting a perfectly clear belt around the horizon, was overcast with a sort of checkerwork of clouds, so thick that the corona could barely be distinguished. During the latter part of totality the very position of the sun was doubtful. Merely to have something to show to prove that the expedition had observed an eclipse, the programme for the intramercurial-planet apparatus was carried through, and the plates were developed. Those exposed in the first half of totality showed the corona faintly, extending out possibly a quarter or half a diameter, and showed the planets Mercury

and Venus. Nothing else could be distinguished, not even the first-magnitude star Aldebaran. The plates exposed during the last half showed even less, as the clouds were then thicker.

The accompanying illustration (Fig. 2) shows the instrument used to obtain the photographs. If the weather had been fine it would have been possible to have obtained photographs which

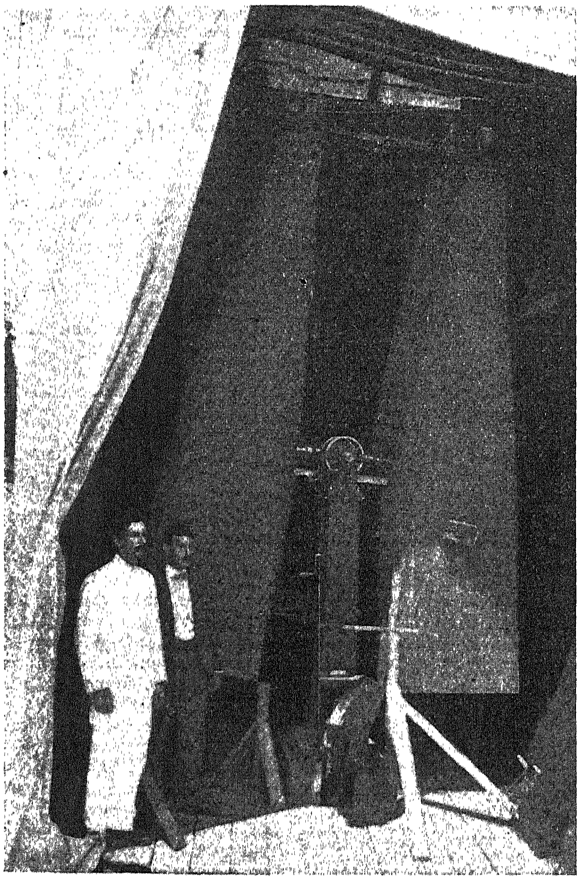

FIG. 2.—The Intra-Mercurial Planet Apparatus of the Smithsonian Institution.

would have decided whether the impressions of the supposed small planets within the orbit of Mercury, which appear upon the photographs of the previous eclipse, represent real bodies or not.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

A FEW particulars of the late Mr. Robert Irvine's bequest for the chair of bacteriology in Edinburgh University are given in the *Lancet*. Certain shares in the Christmas Island Phosphate Co., Ltd., are to form a separate trust to be invested until the property accumulates to the value of 25,000*l*. or 30,000*l*., when the trustees are to pay the sum over to the Association for the better Endowment of the University of Edinburgh, or to such authorities in connection with the University of Edinburgh as the trustees shall deem expedient, for the purpose of founding a professorship of bacteriology in the University and the equipment of a class-room and laboratory for the teaching of the same, and for conducting original investigation in that subject.

FOLLOWING the example of the London Technical Education Board, the Central Welsh Board has arranged for a conference of science teachers, to be held on Thursday, May 15, at the County Buildings, Festiniog. At the morning meeting, papers will be read by Mr. J. Griffith, on "The Teaching of Science as a Preparation for Industrial Life," and Miss Holmer, on "The Value of Biological Teaching for Girls." At the afternoon meeting, papers will be read by Dr. J. J. Findlay, on "The Correlation of the Teaching of Science and Mathematics in Lower Forms," and Mr. W. Saunders, on "Nature Study as an Introduction to Science Teaching." It is hoped that the conference will assist the development of science teaching in Welsh intermediate and technical schools.

AT the Glasgow meeting of the British Association last year, a committee was appointed in connection with the section of Educational Science to consider the conditions of health essential to the carrying on of the work of instruction in schools. The committee is collecting information and tabulating records with reference to original observations on the periods of day appropriate for different studies, the length of lesson, and the periods of study suitable for children of different ages; anthropometrical and physiological observation forms in use in various schools, with a view to prepare a typical form for general use; anthropometrical and physiological observations recorded in different schools for a series of years on the same children; investigations into the causes of defective eyesight in school children and a definition of the conditions necessary for preserving the sight, and the practical knowledge of hygiene possessed by school teachers. Cooperation in obtaining information on these points is invited. Any facts or references relating to the subjects under consideration should be sent to the chairman, Prof. C. S. Sherrington, F.R.S., or to the secretary, Mr. E. White Wallis, 72 Margaret Street, W.

A NOTABLE event, marking the progress made by agricultural education in the States, will take place on July 7, when the first classes of the Graduate School of Agriculture assemble in the Townshend Hall of the Ohio State University. The Graduate School will provide advanced instruction in agricultural science for teachers and investigators. It meets under the auspices of the Ohio State University (where the movement originated), the Department of Agriculture, and the Association of American Agricultural Colleges and Experiment Stations. The session will last for four weeks, and parallel courses of instruction in animal husbandry, dairying, the culture of field crops and other subjects will be given by a special staff of thirty professors and lecturers, including many of the best-known teachers at the American agricultural colleges. The class-rooms, laboratories and apparatus of the Agricultural College of the Ohio State University will be placed at the disposal of this staff. Typical animals will be provided for demonstration purposes, and lectures will be illustrated by specially prepared specimens and diagrams. Admission to the school is limited to graduates, or to persons specially recommended by college authorities. The fee for instruction is six dollars, and the entire cost of the course, apart from travelling expenses, need not exceed thirty dollars.

SCIENTIFIC SERIALS.

American Journal of Science, April.—On the use of the stereographic projection for geographical maps and sailing charts, by S. L. Penfield. In continuation of previous papers on the same subject, the various modes of stereographic projection are described with photographic illustrations from models, with remarks on the use of the stereographic protractor for measuring distances along great circles, of measuring spherical angles at a given point, together with various applications in navigation.—On the hind limb of Protostega, by S. W. Williston. A description of a hind limb of what is probably *P. gigas*, found in the Kansas chalk two years ago. The specimen had for the most part been washed from its matrix, and the original relations of the bones lost. It is characterised by the femur being much more slender than the specimen described by Case.—The physical effects of contact metamorphism, by Joseph Barrel. Although much has been developed in past years concerning the physical, chemical and mineralogical effects of the metamorphism produced in sedimentary beds by the contact of igneous masses, but little has been said concerning the wholesale liberation of gases from the sediments so affected. The shrinkages of volume, the formation of vein fissures, impregnation deposits, and new intrusion

of igneous matter and other phenomena due to this cause are considered in the present paper.—An expedition to the Maldives, by A. Agassiz. The most important result of the expedition was the contribution to our knowledge of atoll formation. The present definition of atolls appears to be unjustifiable, as there is every possible gradation between a curved open crescent-shaped bank of greater or less size and an absolutely closed ring of land surrounding a lagoon without direct communication with the sea.—The flower-like distortion of the coronas due to graded cloudy condensation, by C. Barus.—Varying degrees of actinism of the X-rays, by J. O. Heinze, jun. It was found that the rays which are the most active in producing fluorescence are not those which act most vigorously in the photographic plate, and hence that the maximum effect on a platinocyanide screen does not coincide with the greatest photographic effect.

Bulletin of the American Mathematical Society, March.—The application of the fundamental laws of algebra to the multiplication of infinite series, by Prof. F. Cajori. Following up his previous work (see *Transactions* of the Society, vol. ii. pp. 25–36, and *Science*, vol. xiv., September 13, 1901) and also Pringsheim's (also in vol. ii. of the *Transactions*, pp. 404–412), Prof. Cajori here establishes a class of series with real terms which possesses the property of his former paper, but which seems to be distinct from the class given by Pringsheim. He then considers the validity of the fundamental laws in the multiplication of these infinite series, and next he points out another method for obtaining divergent series whose product is absolutely convergent. Lastly he generalises a theorem of Abel on the multiplication of series.—Dr. Fite gives a notelet concerning the class of a group of order p^m that contains an operator of order p^{m-2} or p^{m-3}, p being a prime.—Dr. Epsteen contributes a proof that the group of an irreducible linear differential equation is transitive.—Another short note follows by Dr. Eisenhart, on lines of length zero on surfaces.—Dr. Kasner, writing on some properties of potential surfaces, extends some of the results of a previous paper (*Bulletin*, vol. vii. pp. 392–9) to the surfaces expressed in rectangular coordinates by an equation $\phi(x, y, z)=0$, where ϕ is a rational integral solution of the potential equation $\Delta\phi \equiv \frac{\delta^2\phi}{\delta x^2}+\frac{\delta^2\phi}{\delta y^2}+\frac{\delta^2\phi}{\delta z^2}=0$. The last four notes were read before the Society and have numerous useful references.—Prof. Osgood gives an extended review of Prof. G. A. Gibson's "Elementary Treatise on the Calculus," in which he remarks that though many teachers may not see their way to use it as a text-book during the early part of the course, yet the book can be commended for collateral reading from the very beginning, and that teachers will have to consider whether it may not be taken as the chief text-book in the second course.—Further short notices follow of Cahen's "Éléments de la Théorie des Nombres" and of R. Dedekind's "Essays on the Theory of Numbers" (Beman's translation) by Prof. L. E. Dickson, and of the "Annuaire pour l'An 1902" by Prof. E. W. Brown.

Memoirs of the St. Petersburg Society of Naturalists, Botany, vol. xxx.—On parasite fungi found in the neighbourhoods of St. Petersburg, by K. S. Ivanoff. List of 153 species, with a few remarks.—Critical review of the flora of Moscow, by A. N. Petunnikoff. Second part, continued from *Botanicheskiya Zapiski*, part xiii., 1896; full summary in German.—Botanical researches in the province of Orel, by M. D. Zalessky; summary in German. A portion of this paper is given to a detailed description of a Scotch-fir forest on a Loess soil, which is a rare case in Russia, and which the author explains in accordance with the views of Litwinow (*Bull. Soc. Nat. Moscou*, 1890, No. 3) on the survival of fir forests during the great Pleistocene glaciation.—On dormant buds, by W. Lubimenko, with twenty-nine figures; summary in German.—Exploration of the flora of Pskov in 1899–1900, by N. Puring.—The flora of the Polyesie, by Joseph Paczosski, continued. The Monocotyledones, Nos. 951 to 1291, are now given, and this most valuable work is thus concluded.

Vol. xxxi.—The whole of this volume is given to the first and the second fascicules of "Flora Caucasica Critica," by N. Kuznetsoff, N. Busch and A. Fomin. The intention of the authors is to give, in a series of monographs disposed in the same system as in A. Engler's "Pflanzenfamilien," the necessary materials for an abridged "Flora of the Caucasus." This latter would be for general use, while the present work must be a sort of preparatory work for specialists only. The successful accomplishment of this grand undertaking seems to be guaranteed—the editor, Prof. Kuznetsoff, having reasons to believe that the work will find the support of specialists. We may remark that under the heading of habitus we find for certain species extremely valuable and most interesting descriptions, which will be welcome to both the systematist and the geographer. The present volume includes the Pirolaceæ, Ericaceæ and Primulaceæ, by Kuznetsoff, and the Nymphaceæ, Ceratophyllaceæ and Ranunculaceæ, by Busch.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, November 28, 1901.—"A Comparative Study of the Spectra, Densities and Melting Points of some Groups of Elements, and of the Relation of Properties to Atomic Mass." By Hugh Ramage, B.A., A.R.C.Sc.I., St. John's College, Cambridge. Communicated by Prof. G. D. Liveing, F.R.S.

The properties of nineteen elements were studied, namely:—(1) Lithium, sodium, potassium, rubidium, cæsium; (2) copper, silver, gold; (3) magnesium, zinc, cadmium, mercury; (4) calcium, strontium, barium; (5) aluminium, gallium, indium and thallium. The flame spectra of the metals are much simpler than the arc or spark spectra; they may be regarded as the fundamental spectra of the metals. They furnish purely experimental data with which to begin an investigation of the laws which govern the distribution of lines in spectra and by which to study the relations of the physical and chemical properties of the metals to their spectra. Diagrams were drawn with the oscillation frequencies of the lines in the fundamental spectra, or the densities, or the melting points, of the metals as abscissæ, and the atomic masses, or a function of these, as ordinates. Two diagrams of spectra are reproduced in the paper. The corresponding lines in homologous spectra were joined by lines some of which are straight, but most are curved. The densities and melting points were connected in a similar way.

The following facts have been observed in the study of the diagrams:—

(1) The metals considered may be classified into groups according to the characters of their spectra. The elements in each group appear to have a similar atomic constitution.

(2) The connecting lines between the members of the chemical groups are not continuous; there are certain breaks in them. These occur between the metals sodium, magnesium and aluminium, and the metals of their respective groups with higher atomic masses. The break between the sharp series in the spectra of the aluminium group is very slight; that between the diffuse series is very marked and corresponds to marked changes in the densities and melting points of these elements.

(3) The cause of the displacement of corresponding lines in some strictly homologous spectra is intimately connected with the atomic masses. The shift of the subordinate series of potassium, rubidium and cæsium is approximately proportional to the atomic mass, whilst the shift of the principal series is very nearly proportional to the square of the atomic mass.

(4) The second diagram, drawn from the spectra and the squares of the atomic masses, shows that the lines which connect the corresponding members of homologous doublets and triplets approach one another as the atomic mass decreases and intersect on the line of zero atomic mass.

The spectra of potassium, rubidium and cæsium change regularly with the atomic mass, and it should be possible to express the series in these spectra by a formula in which the atomic mass is the only variable. There are obvious difficulties in modifying Kayser and Runge's formula in this way, but Rydberg's formula is more general and the constants are more easily calculated. Rydberg's formula and method give better results for the subordinate series than for the principal series; also for the series in the spectra of elements of low atomic mass than for those of high. The best results were obtained for the principal series of the three metals when in Rydberg's general formula

$$n=n_\infty - \frac{N_0}{(m+\mu)^2}$$

we substituted

$$n_{\infty}=35349-aW^2;\ N_0=109675$$

and

$$\mu=\{1\cdot19126+0\cdot00103W+(0\cdot04377+13W^2\times10^{-})(1-3^{1-m})\},$$

where

$$n=10^8\lambda^{-1};\ a=0\cdot2233;\ W=\text{atomic mass, and } m=1,2,3\ldots$$

This formula gives the second principal series of the three metals; the first principal series are obtained by increasing the value of μ by $182W^2\times10^{-8}$. The agreement between the observed and calculated numbers is very close. The formula, though empirical, involves only seven adjustable constants, and it represents in the table, given in the paper, thirty-two lines. It thus affords striking evidence for the fundamental identity of type of the spectra of the three metals to which it applies, and indicates that their differences depend on the atomic mass alone. This evidence is further strengthened when it is remembered that, being only an approximation to an unknown formula, it will naturally come nearer it for large values of m than for small ones. Additional evidence supporting these views is given by the above observations upon the subordinate series of these three metals. The fundamental lines in the spectra of calcium, strontium and barium are given by the formula

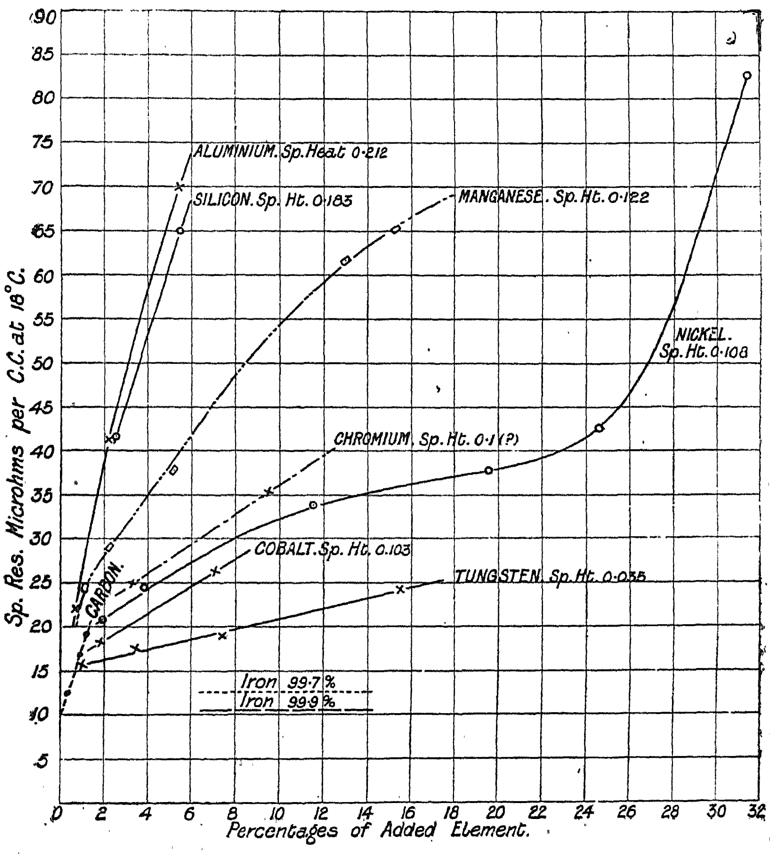
$$n=24170-0\cdot3232W^2.$$

Many points of interest are revealed by a study of these diagrams, but perhaps the greatest interest lies in the comprehensive view one gets of the order of change in the properties of the elements. The diagram of densities is easier to understand than that of melting points, and the double connections in it, from sodium to potassium and copper, from magnesium to calcium and zinc and from aluminium to scandium and gallium, are seen to be quite natural. The changes in some of the corresponding lines in the spectra agree with the changes in the densities and melting points of the elements. Other lines in the same spectra change in a manner which is independent of these.

The whole study indicates that the properties of the elements are fundamentally due to the structure of the atoms as revealed by their spectra rather than to the quantity of matter in them. It seems, for instance, inconceivable that the transition from calcium to strontium proceeded through the intermediate elements when we consider that the strontium atoms must have a similar structure to those of calcium, and that this structure is so simple that the fundamental spectrum of each of these elements consists of a single line. The anomaly, according to Mendeléeff's law, in the atomic masses of tellurium and iodine is further evidence of this. The genesis was not in the direction of tellurium to iodine, but from, or perhaps through, oxygen and fluorine respectively.

February 6.—On the increase of electrical resistivity caused by alloying iron with various elements to the specific heat of those elements. By Prof. W. F. Barrett, F.R.S.

In this paper the author draws attention to a connection which appears to exist between the electric conductivity of certain alloys of iron and the specific heats, and hence atomic masses, of the particular elements with which the iron is alloyed. In previous memoirs, the author, in conjunction with Mr. W. Brown, has determined the electric conductivity and magnetic permeability of 110 different alloys of iron prepared with great care by Mr. R. A. Hadfield, of Sheffield.[1] The results of these experiments show (1) that the conductivity of iron is diminished by alloying it with another metal even though that metal be a much better conductor than iron; (2) that this reduction of conductivity is not related to the resistivity of the added metal; on the contrary, an alloy of very high specific resistance can be produced by adding to iron an element of much lower specific resistance than the iron itself, *e.g.* the metal aluminium is upwards of three times better a conductor than iron, yet the addition of 5 per cent. of aluminium to iron makes the conductivity of the alloy five times worse than iron; (3) the greatest reduction in conductivity in a given alloy is produced by the first increments of the added element. This is shown in the accompanying diagram, where the specific resistances of some of the alloys examined (deduced from their conductivities), are plotted against the percentages of the added element: the specific resistance of iron alone being shown by the horizontal dotted lines, the upper containing 0·3 and the lower only 0·1 per cent. of carbon and other foreign bodies. The series of fairly smooth curves thus obtained for each alloy are seen to be steepest near their origin, a curious flexure being



found in the nickel steels; (4) a relationship does appear to exist between the specific heat of the added element and the resistance of the alloy it forms when united with iron. In the diagram the specific heats of the various elements are placed after their names. Thus the specific resistance of an alloy of $5\frac{1}{2}$ per cent. of aluminium with iron is seen to be 70 microhms, the same amount of silicon with iron 65 microhms, of manganese with iron 38 microhms, of nickel 27 microhms, and of tungsten 18 microhms; now the specific heats of these elements are, aluminium 0·212, silicon 0·183, manganese 0·122, nickel 0·109, and tungsten 0·035. Those elements having high specific heats, and therefore small atomic or molecular masses, produce the greatest increase in electric resistivity of the corresponding alloy with iron.

Dividing the *increase* in electric resistivity by the percentage of the added metal, we obtain the increase in the specific resistance of iron produced by 1 per cent. of the added element

[1] *Scientific Transactions of the Royal Dublin Society*, vols. vii. and viii. "Researches on the Physical Properties of the Alloys of Iron," by W. F. Barrett, W. Brown and R. A. Hadfield.

various temperatures, and by the application of the formula of Clapeyron to the data thus obtained, the heat of formation of the hydride is calculated, and compared with the value given by direct experiment. From these experiments it was also possible to give the exact conditions necessary to the preparation of metallic strontium from its amalgam.—On the combinations of alumina with chromium sesquioxide, by M. Duboin.—On the composition of the amidotariric acids, by M. Arnaud. The application of Beckmann's reaction to tariric ketoxime gave undecylamine, pimelic acid, lauric acid and amidocaproic acid, from which the formula $CH_3—(CH_2)_{10}—C\equiv C—(CH_2)_4—CO_2H$ is deduced for tariric acid.—On diacetylbenzoylethane and acetylmethylphenylfurfurane, by M. F. March.—On methoethenylbenzene, by M. M. Tiffenau.—On oxyisopropylphosphinic acid, by M. C. Marie.—The action of the organo-magnesium compounds on the β-ketonic esters, by M. V. Grignard. Acetoacetic ethyl ester reacts with magnesium methyl iodide entirely in the enolic form; its mono-alkyl derivatives appear to behave as a mixture of the enolic and ketonic forms; the product of condensation of acetoacetic ester with aldehydes react with the magnesium alkyl compounds in a manner corresponding to the formula of Classen.—On the ichthyological fauna of the basin of the Adour, by M. G. de Saint-Paul.—On the epithelio-glandular origin of the seminal cells, by M. G. Loisel. The conclusion is drawn from the experiments cited that in all vertebrates, including mammals, birds, reptiles and fishes, the seminal cells are derived from a glandular epithelium.—On the generic identity of *Zygodia axillaris* and the *Baissea*, by M. Henri Hua.—The treatment of rickets by cod liver oil containing lecithin, by M. G. Carriere. The cod liver oil used contained 0·41 per cent. of lecithin derived from eggs, and was applied in five cases, with the result that the disease was arrested and cured in from four to six months.—Researches in the variations arising in the toxic power of certain mineral and organic compounds, according to the chemical groups to which they are linked in their soluble compounds, by M. Marc Laffont.

SUPPLEMENT TO "NATURE."

FIRST FRUITS OF THE CAMBRIDGE ANTHROPOLOGICAL EXPEDITION TO TORRES STRAITS.

Head-Hunters, Black, White and Brown. By Alfred C. Haddon, Sc.D., F.R.S. Pp. xxiv + 426. (London: Methuen and Co., 1901.) Price 15*s.*

UNDER this sporting title, Dr. Haddon has published a preliminary and popular account of the Cambridge Anthropological Expedition to Torres Straits and its unofficial extension to Sarawak. Expeditions for various scientific purposes have long been familiar. Expeditions for specifically anthropological purposes have been frequently organised in the United States and in Germany; but in this country such an expedition is a "new departure." Contributions to the cost of the Torres Straits Expedition came from more than one source; the chief part of the funds, however, was supplied by the University of Cambridge—hence the name. The expedition was led by Dr. Haddon, whose interest in the natives had been excited ten years before, when he visited the islands of Torres Straits on a scientific mission of a different character. He secured as colleagues Dr. W. H. R. Rivers, Dr. C. S. Myers, Mr. W. McDougall, Mr. Sidney H. Ray, Mr. C. G. Seligmann and the late Mr. Anthony Wilkin—the majority of them Cambridge men. They left London on March 10, 1898, and the last of them returned on May 31 in the following year. Nearly seven months were spent by most of them in Torres Straits, on the islands and on the mainland of New Guinea, with a short visit to the contiguous part of Australia. Upwards of four months were spent by the leader of the expedition, Mr. Ray and Mr. Seligmann at Sarawak, whither Dr. Myers and Mr. McDougall had preceded them.

The object of the expedition was not merely to investigate the physical and mental development of the islanders of Torres Straits, but to determine, if possible, their ethnological position, situated as they are geographically between the Papuans and Melanesians of New Guinea and the islands further to the eastward, on the one hand, and the Australian race on the other. The result has been to trace the population wholly to the north and east, without any recognisable admixture of the Australian element, although many of the islands, and those the largest, are within a few miles of Cape York. The amount of work done in the way of physical observations, mental tests and investigations into the civilisation of the natives will only be rendered appreciable when the official reports are complete. A very slight examination, however, of the part (by Dr. Rivers) which has already been issued will suffice to convince everyone of the extreme care with which the inquiries were conducted, and of the value of the information obtained as data for induction and as a guide for future researches.

The fact that the islanders have been under continuous European influence for a quarter of a century rendered them more docile and capable of assisting the investigations into their physical and mental qualities. But it had the inevitable disadvantage that their customs were undergoing rapid change; many interesting ceremonies and institutions had been abandoned; the old lore and many of the old superstitions were beginning to be forgotten; the shrines of the ancient worship were neglected or desecrated; and European clothing and mission churches were outward and visible signs of the new order. It is true this change was not without its compensations. Communication was made easier by the fact that nearly all the natives knew some pidgin English, as well as by their comparative familiarity with the ways of white men. But again and again things of importance that had been recoverable even ten years previously had vanished. Old men, the depositories of tradition, had died. Ceremonies which the travellers witnessed were often only make-shift and imperfect representations performed for their special behoof, and had to be supplemented by explanations, too often, doubtless, as imperfect as the representations. "It was very saddening," says Dr. Haddon, "to be continually pulled up in our researches by the oft-repeated cry of '*Too late!*'" In spite of all this, however, much survived. Amusing instances are given, showing how the old superstitions lingered in the minds of those who had renounced them and who were doing their best to lead Christian lives according to the standard of their missionary instructors.

Dr. Haddon's narrative of the expedition contains some very entertaining chapters, and some excellent stories of the natives and of the stratagems resorted to by the travellers to obtain the information they were seeking. One of the quaintest things is the account of a missionary meeting on the island of Mabuiag, which Dr. Haddon was suddenly called on to address. After the meeting was over, a war-dance was performed by some of the natives for the delectation of the scientific visitors. It was called Kwoiam's dance, after the mythical hero of the island. Men who had been singing hymns, and evincing their genuine interest in the mission by giving what were really substantial sums of money for the evangelisation of New Guinea, painted themselves with red and black and yellow ochre, adorned themselves with cocoa-nut leaves, and carried bows and arrows and (to represent decapitated human heads, such as they once had borne in grim earnest) cocoa-nuts and pawpaws. So vivid was the representation that in the course of the dance "some old women, excited by the memory of former days, could not refrain from joining also." "Imagine," exclaims the author, "a 'May meeting' in Exeter Hall closing with a war-dance!"

The narrative also contains incidentally pregnant hints for future anthropological explorers. But, on the whole, its interest is secondary to that of the ethnographical information interspersed or set forth in special chapters. Some of this is of high value, though probably not expanded as fully as it will be in the official report. The subject of totemism has during recent years occupied a large space in the discussions concerning the evolution of religion and of social institutions. Until we see the details of Dr. Haddon's discoveries it is, perhaps, premature to say that they will settle any of the questions to which it has given rise. But enough appears in the volume

before us to satisfy us of the importance of these discoveries. They point to the economic value of totemism, in which Dr Frazer has suggested its origin is to be found. The dugong-clan on Mabuiag seem to have performed rites to secure plenty of dugongs, the turtle-men to secure plenty of turtles. The office of rain-maker is said to be hereditary in a certain family, though to what clan it belonged and what position it occupied in the clan we are not yet told. The localisation of the totemic ceremonies, the use of the same word (*augŭd*) to mean the totem itself, the sacred objects used in the ceremonies, and a human ancestral (though probably mythical) hero suggest that totemism was passing into the worship of ancestors, or at least into hero-worship, "and a hero-worship that is suspiciously like the origin of a god." Not less important than the meaning and development of totemism is the delimitation of its area. Here, too, good work has been done. Although totemism was flourishing in the western islands of the Straits and bore evidence that it had been brought with the immigration from New Guinea, the travellers failed to trace it in some of the powerful stocks of British New Guinea; they ascertained that there was no true totemism in the eastern islands, and their researches in Borneo seem definitely to negative any connection between the animal-cult of the tribes in Sarawak and totemism.

Where the totem-clan does not exist, a point of great interest is the organisation of society and the conception of relationships. On this we are told nothing directly. We learn, however, that Dr. Rivers made minute inquiries into the genealogy of the Murray Islanders and some other peoples. It is to be hoped that when these are published we shall have some data for inferences, not merely as to hereditary qualities, but also as to social relations.

Interesting as the chapters relating to Torres Straits and New Guinea are, those which narrate the author's experiences in Borneo and discuss some of the superstitions practised there are in no way inferior. Balan's love-story is delightful, and the chapter on the peace-making at Baram forms an artistic conclusion to the mission. On the omen-animals Dr. Haddon is able to contribute some additional facts to our knowledge, as well as to describe the ceremonies he witnessed. The chapter on the cult of skulls, and the scenes in which he was an actor as the purchaser of skulls, are perhaps even more suggestive. We learn that the practice of taking skulls is not an ancient one among the Kayans and Kenyahs, two of the larger and more influential tribes. We are told that "some tribes believe that the persons whose heads they take will become their slaves in the next world," and that the vendetta is a common reason for the hunt of heads. But Dr. Haddon expresses no opinion on the origin and real meaning of the custom. Mr. Kruyt, a Dutch *savant*, has recently published an account of it as practised by the Toradja of Central Celebes. In that neighbouring island it would seem that the tribe referred to recognise a three-fold soul in every living being. There is, first, the breath; secondly, the personal soul; and lastly, a part of the universal soul or vital ether. It is the last which is attached to the skull and the scalp of man and other animals. To procure the skull, therefore, is to render oneself the possessor of the victim's share of the vital ether. By depositing it in the shrine of the ancestral gods, this share is offered to them. As the gods appear to be the manes of ancestors, the possession of this share of the vital ether fortifies the vital ether of the family or the clan; in other words, their portion of the universal soul is augmented. Mr. Kruyt, after examining the beliefs and customs of the Dayaks and Battaks, comes to the conclusion that their head-hunting is based upon substantially the same belief. We shall be glad to know whether Dr. Haddon has observed any facts which corroborate this theory.

The volume is adorned with numerous reproductions of photographs by the author and his colleagues, as well as by many sketches. The photographs are for the most part good, some excellent. In many cases, however, the reproduction is on too small a scale for proper exhibition of the details.

Full of interest for the general public, the volume is admirably calculated to awaken scientific curiosity and bespeak attention for the detailed results of the expedition, now in course of publication by the University Press.

E. SIDNEY HARTLAND.

THE SEA-COAST OF ENGLAND.

The Sea-coast: (1) *Destruction*, (2) *Littoral Drift*, (3) *Protection*. By W. H. Wheeler, M.Inst.C.E. Pp. xii + 361. (London: Longmans, Green and Co., 1902.) Price 10*s*. 6*d*. net.

THE sea-coast is always a fascinating object to the hydraulic engineer, for besides the varieties of its conditions, it is the place where the most vehement attacks of the orces of nature have to be encountered and provided against. The sea is an ever-present foe, the power of which when lashed into waves by gales is almost incalculable, always quick to pierce any weak point in the defences and to push forward its advantage by enlarging the breach, and sometimes producing widespread ruin before the initial damage can be repaired. Moreover, in some cases, the protection of one part of the coast leads to the weakening of an adjacent portion, and the sea, foiled in a direct attack, overcomes opposition by a sort of flank movement on an unprotected place. On some coasts the gradual advance of the sea can only be checked for a time; and the erosion of the cliffs during storms is promoted by the disintegrating action of rain and frost, the débris being scattered over the beach and eventually carried away by littoral drift. The rate of encroachment of the sea depends mainly on the exposure of the coast, the slope of the beach and foreshore, and the nature of the cliffs or shore; for on a very open sea-coast exposed to strong winds, with deep water near the shore, the erosive action of the large waves rolling in is very great, especially when breaking against cliffs composed of clay or other readily disintegrated materials. Irresistible secular changes appear to be taking place along some coasts, for a slow but steady advance of the sea may be noted in some places, and a distinct retrogression observed in other parts. The protection of land against the ravages of the sea must depend upon the value of the land and its position. Where villages and towns have been built alongside the sea-coast, large sums may be advantageously expended

in securing such valuable sites from injury, and in forming and preserving promenades in front of them; and where low-lying or reclaimed lands, extending a considerable distance inland, are protected by sea banks, it is very important that these barriers against extensive inundations should be efficiently maintained. In places, however, where long stretches of agricultural land, well above sea-level, bordering the sea-coast are subject to gradual erosion, the cost of adequately protective works would amount to more than the value of the land lost.

The author has for many years taken an interest in the changes taking place along the coasts of England, and the results of the various means adopted at different places for their protection; and his researches into records and observations of littoral drift, the action of waves and tides, sea-coast protection, and shingle-banks and sand beaches have formed the subjects of papers read at the Institution of Civil Engineers and meetings of the British Association, and articles contributed to *The Engineer* and this Journal, which have been collected together to form the present book. The subjects are dealt with under three general heads, namely, (1) "Destruction," (2) "Littoral Drift," and (3) "Protection." After a short introductory chapter, the first head is considered in a single chapter on "The Action of Shore Waves"; the second head forms the title and the subject of the following chapter; whilst the protection of the sea-coast is dealt with in three chapters, two relating to sea-walls and the third to groynes. These matters, however, occupy barely more than one-third of the book, and the remainder of the volume is taken up with an inordinately long chapter of above two hundred pages, giving details of the south, east, and west coasts of England, and a comparatively short chapter on the coasts of northern France, Belgium and Holland. These two last chapters constitute an elaborate compilation of facts concerning the sea-coasts referred to, collected from various publications, including naturally the reports and numerous data obtained by the Coast Erosion Committee of the British Association, and also the author's own observations, which should prove useful for reference; but the main interest is comprised in the earlier portion of the book, which embraces the chief object of its publication.

In the chapter on the action of shore waves, the author propounds his theory that the main agent of the littoral drift observed along our coasts is tidal action, and that storm waves are only auxiliary agents of quite minor importance; and he restates this view with greater emphasis, as an established fact, towards the close of the following chapter, on littoral drift, in these words (p. 75):—

"As already mentioned, the agent which is instrumental in building up shingle into banks and transporting it along the coast is the tide, which accomplishes this by means of the waves which are for ever breaking on the beach as the tide rises and falls. The formation and action of tidal shore wavelets has been already described in the chapter on wave-action. These wavelets, aided by the flood current, lift up and carry forward any coarse sand, loose stones, or other material with which they come in contact, and leave some portion of them stranded at the highest point on the beach to which the tide of the day reaches."

In a paper on "Littoral Drift," read at the Institution of Civil Engineers in 1896, Mr. Wheeler enunciated this theory, and in the discussion which followed, remarkable unanimity was manifested by the speakers in dissenting wholly from this view; and it may reasonably be surmised that the author hopes that acceptance of his theory, which was on that occasion denied him by the persons most conversant with the subject, may, when brought forward in the sort of authoritative form of a book, be granted him by the general public. His notion of the power of tidal action is evidently in some measure due to his assumption that the tidal wave is a wave of translation, with the entire body of water composing it in motion throughout its whole depth; and he does not realise that this would involve a continuous movement of the sea in one direction, at the rate of progression of the tidal wave, which in the Pacific Ocean, the cradle of the tides, amounts to about 1000 miles an hour, and even in the English Channel reaches about 55 miles an hour; whilst the clashing together, off the mouth of the Thames, of two of these waves of translation coming from opposite directions would be a remarkable sight. The author, moreover, in attributing littoral drift to the action of the wavelets of the flood tide along the shore, appears to ignore the reverse action of the ebb; though in referring to the effect of tidal currents on submerged sand-beds in channels, he points out that their "movement is one of oscillation and not transportation." A great number of instances might be cited of littoral currents and littoral drift which, in the absence of a tide, could not possibly be attributed to tidal action, as, for example, the littoral movement across the face of the delta of the Mississippi in the almost tideless Gulf of Mexico, the drift which occurs in various places along the shores of the Mediterranean, and the littoral current which diverts towards the south the alluvium issuing from the mouths of the Danube in the Black Sea. The author tries to strengthen his contention as to the paramount effect of the flood tide by ascribing wind waves, the power and influence of which are extended landwards by the increased depth at high water, to tidal action. Thus under the heading of "Tidal Waves" he says:—

"In the great majority of cases the waves which affect beaches, cliffs, and sea-walls are those which occur when the rise of the tide affords the necessary depth of water for their formation. . . . The maximum effect due to the tidal wave is felt at the time of high spring tides, when accompanied by heavy on-shore gales."

Further on also the following passage occurs:—

"Even when the depth of water in front of a sea-wall or cliff is only that due to the rise of tide, water from waves that break is thrown to very great heights. Thus at Hastings, where the beach at the foot of the sea-wall is dry at low water, and the depth of the water is only that due to a rise of 15 feet at high water, during a heavy gale in the winter of 1898 the broken water was thrown as high as the top of a large hotel, as shown in the frontispiece, and shingle was lifted off the beach and carried across the promenade into the bedrooms of the houses fronting the sea. At Peterhead, as already mentioned, the water due to a rise of tide on the foreshore of only 7 or 8 feet has been known to strike the wall with such force as to be thrown upwards 100 feet."

It is certain that the inhabitants of Hastings will have attributed the striking phenomenon illustrated in the book

to its true cause, the gale, aided undoubtedly by the raised water-level, due partly to the tide, and also partly to the heaping up of the sea against a lee shore by an on-shore gale; whilst the wave-stroke at Peterhead was not due, as implied above, to a tidal rise of 8 feet, but, as mentioned a few pages earlier, to the depth into which the breakwater has been carried, the great exposure of the site, and the large waves, attaining 30 feet in height and 600 feet in length during storms, which, consequently, come against the structure.

Numerous instances have been frankly quoted in the two chapters on wave action and littoral drift of the effect of waves in storms in transporting material along the coast, reference to two of which must suffice:—

"In the Solent, near Hurst Castle, a shingle bank, 2 miles long and 12 feet high, consisting principally of flints resting on a clay base, was moved forward in a north-easterly direction forty yards during a storm in 1824. . . . During a heavy gale stones weighing from 2 to 3 cwt., with large masses of seaweed growing on them, were loosened from their bed at a depth of fifteen fathoms, and thrown on to the beach."

Compared with the forces displayed by these effects, and the others given in the book produced by waves in storms, the wavelets of the flood tide sink into insignificance; and, thanks to the fairness with which these examples have been given, it may be anticipated that an unbiassed, intelligent perusal of these two chapters will lead to conclusions at variance with those of the author, and that it will be realised that waves in storms are the chief forces producing changes in coasts and littoral drift, exercising their maximum effect during high water of spring tides, and when acting in unison with the tidal currents.

From an engineering point of view, the most interesting part of the book is comprised in the three chapters on coast protection by sea-walls and groynes. Sea-walls formed of embankments with pitched slopes, or more or less upright masonry or concrete walls, serve for directly warding off the attacks of the waves in storms from the shore, cliffs, or sea-drives and promenades; whilst groynes of timber, fascines, or concrete are projected at intervals down the beach to arrest the littoral drift, and by thus gradually raising the strand prevent the sea from eroding the shore. Unfortunately groynes, by collecting the drift along one part of the beach, deprive the unprotected portion further leeward of the supply by which its losses by erosion would be naturally replenished; and, consequently, the advance of a length of foreshore produced by groynes is accompanied by a retrogression of the adjacent portion from the cutting off of the drift. A pitched slope is adopted where the shore to be protected is low and sandy, and where materials for a wall are deficient, as along the coasts of Holland and Belgium; and a wall is resorted to where cliffs line the coast, or a sea-drive is constructed considerably above the beach; and this variety in construction is due to differences in, the conditions rather than, as suggested by the author to differences of opinion amongst engineers. A simple upright wall has advantages for breakwaters over other forms where the bottom is rocky and the depth moderate; but in contrasting Dover pier, which has not been free from injury, with the breakwaters at Cherbourg, Plymouth, and Alderney, the author has fallen into a very common error of overlooking the differences of exposure and depth of water at these sites; for Dover is situated in one of the most sheltered places of the English Channel, whereas Cherbourg is much more exposed, and the breakwaters of Plymouth and Alderney are open to the Atlantic, and the latter extends into a depth of 130 feet at low water. Sea-walls, however, differ very materially from breakwaters in being built near high-water mark, and therefore upright sea-walls are subject to considerable erosion at their toe, from the recoil of the waves dashing against them, which affects even chalk and shale, so that unless the foreshore consists of firm rock, the sea-wall, which is usually curved or battered on the face, has to be founded below the limit of erosion, or more commonly is provided with an apron to protect the portion of the beach near the sea-wall from the breaking and recoiling waves. A stepped face is sometimes given to sea-walls, so as to impede the upward run of the waves and break up the recoil; but the work must be solidly built, and only a moderate width given to the steps, otherwise the reduction of the weight on the face blocks due to their projection might lead to their dislocation under the impact of the waves. The author regards a sea-wall curving on its face from the apron laid at the slope of the beach, to the vertical at the top, as the best form, and no doubt such a form leads the waves from a horizontal to a vertical course with the least practicable opposition; but at the same time, by minimising the impediments, it causes the waves to rise higher above the wall, and the upper portion of the water is driven over the promenade by the gale. In the chapter on "Examples of Sea-walls," several sections of sea-walls are given; and both this and the succeeding chapter on "Groynes" contain many interesting details of these works; and the book as a whole furnishes a considerable amount of information about the coasts of England, which must have involved much time and trouble to collect.

EVOLUTION AND ANTI-MATERIALISM.

Principles of Western Civilisation. By Benjamin Kidd. Pp. vi+518. (London: Macmillan and Co., Ltd., 1902.) Price 15*s.* net.

TO those who, some years back, read Mr. Benjamin Kidd's "Social Evolution" with great interest and learnt much from it, his new book will be a profound disappointment. Undertaking to settle all the great questions with which our civilisation is confronted, it leaves many important facts out of sight and fails to find a remedy for the main evils. The style is ponderous and difficult. In some parts very careful reading is required if the exact meaning is to be made out.

The line of argument followed is this. Evolution has upset all our old philosophies and obliged us to remodel our way of thinking. Since Darwin's time, evolution has undergone a great development in the hands of Weismann. We now see that the future is predominant over the present. The overwhelming proportion of individuals interested in the struggle for existence are yet unborn. The contending races are struggling for "an advantage, probably always far in the future, to which the individual

and the present are alike subordinated." In the struggle, "efficiency in the future" (described as "projected efficiency") "is the determining quality," and so the future controls the present.

There are two epochs of social development. In the former of the two, the existing social organisation counted for everything. In the second, "society, with all its interests in the present, is subordinated to its own future." "Projected efficiency" is the secret of success and of progress. The want of it causes stagnation. In the city States of ancient Greece and in ancient Rome, the present was omnipotent. Marcus Aurelius, noble character as he was, represented a decaying system, bounded by the present. With the spread of Christianity, the horizon enlarges and the future becomes predominant. "The visions of Christianity can never be closed within any limitations of the State or of political consciousness." Turning to politics, we find in England at the time of the Revolution a looking beyond the present to the future. But during a later period our philosophers professed creeds that left out of consideration everything that lay beyond the horizon of the present. Bentham, Ricardo, Mill, Herbert Spencer are interested only in living individuals and their relation to the State. On the other hand, Burke says that society is a partnership "between those who are living and those who are dead and those who are to be born." In Germany, progress is hampered by a frankly materialistic philosophy, the philosophy of Marx, which takes no thought of generations yet to come. Among English-speaking peoples there is a conviction that "the principles of the Democracy which our civilisation is destined to realise are incompatible with a materialistic interpretation of history." We look to the future and not to the present. Hence the marvellous progress of our race, in spite of the fact that the average Englishman is averse to liberal ideas. An age of the free-est competition is beginning, from which immeasurable results may be expected. The present astounding expansion of the English-speaking race is as nothing compared with what is to be. And this magnificent future will be due to free competition, which will not be disgraced by the oppression of the workman by the capitalist, or by the barbarism of our present commercial methods. The predominance of the future will make all this possible. The evolutionary process will be projected altogether beyond the present.

All these theories seem to have their origin in Mr. Kidd's strong anti-materialistic convictions. His formula of the future (to propose a brief name for it), which forms the central doctrine of his creed, serves to unite his anti-materialism with the theory of evolution, which, as he maintains, must now be the foundation of all philosophy. A formula that embraces evolution and transcendental anti-materialism must, of necessity, be very vague. The predominance of the future is, therefore, stated in very indefinite terms, so that it may include things which are essentially different. Thus, evolution regards the future of the race—unborn generations—as of the utmost importance. Christianity puts the future life of the individual above his present life. These two views in a mist of grand phrases are put down as the same, or at least as different aspects of the same, truth. The treatment of philosophical systems seems to involve the same confusion of thought. For evolution, Mr. Kidd says, the unborn generations are everything. Evolution, as we all know, is, largely, independent and will go on whatever our philosophy may be; and yet the views of this or that philosopher are treated as of supreme importance, as if the fate of the nation to which he belonge were involved in them.

When we come to the most interesting and best-written chapters, those in which modern trade and its methods are described, there is again much confusion in the theories which are built upon the facts. Competition, especially in America, is more free than it has ever been before. In the future, we are told, there will be still greater freedom. Yet the fierceness of competition is to be held in check by humane laws which will protect the workman from oppression. Capital, too, will not be allowed to exploit the nation for its own advantage. This is an admirable ideal. But how is it to be combined with a freedom of competition such as has never been known before? Mr. Kidd does not help us here. We are only told that to the English-speaking peoples, free as they are from materialism, everything will be possible. Here we may ask a question:—If anti-materialism is the one secret of progress, how is it that in the East, the birthplace of all the great religions, stagnation is the rule?

We feel much the want of some sound biology. Mr. Kidd adopts some of Weismann's most disputed theories, such as that of the immortality of the unicellular organisms. But other views of Weismann's which conflict with his own theories he says nothing about. Weismann holds, for instance, that as soon as the stress of natural selection is relaxed, a species begins to lose the powers that it has gained. It degenerates. Now, this era of free competition, seen at its best in the United States, is really a time of slackening natural selection. Children are cared for better than ever before, so that many of the weakly survive. The deaf are so well taught that they can make a living and marry, and so leave deaf descendants. The competition, in fact, whether between peoples or individuals, does not lead to elimination. The conditions of life have grown softer, and under such conditions there must be, if there is truth in Weismann's contention, physical degeneration, though it may be screened by the constant influx of numbers of the more vigorous members of the European peoples into the New World. On this subject Mr. Kidd does not touch. Yet the tendency to physical degeneration, more than any other phenomenon of our time, causes anxiety to those who watch the drift of our modern civilisation.

Again, as to the main idea of the book, how is it possible that efficiency in the future, "projected efficiency," can decide a struggle that has to be fought out in the present? It is true that some classes of animals, having succeeded in one period in virtue of their specialisation, have, probably because they were so highly specialised, been unable to take a new line and meet new demands made upon them in the succeeding period. But, apparently, this is not what Mr. Kidd means. His formula is made to refer to evolution as it refers to systems of philosophy or to creeds in which the supremely important future controls the present. He owns that the contending races must fight their battles

in the present, and yet in some unexplained way "projected efficiency" decides the issue. When we look facts in the face we find that our anti-materialistic philosophy is not saving us from entering upon the same ruinous course on which the French nation has already proceeded far. Our diminishing birthrate shows that there has already begun among our people that artificial limitation of fertility which must, if it continues, bring national decline with it.

We all wish that these evils should come to an end and that the English-speaking peoples should have a magnificent future before them. Towards this, no doubt, an anti-materialistic philosophy is a help. Materialism is incompatible with real greatness in an individual or a nation. So far we may go with Mr. Kidd. But we cannot allow that he has found a formula in which all our great problems—the problems of evolution, civilisation, religion—find their solution. The problems remain as they were. F. W. H.

GALLS.

British Vegetable Galls, an Introduction to their Study By E. T. Connold. Pp. xi + 312. (London: Hutchinson and Co., 1901.) Price 10*s.* 6*d.* net.

THIS beautiful book is a great disappointment. The title, the nice paper, with its broad margin and excellent print, and, above all, the majority of the one hundred and thirty full-page plates paraded, and by no means unjustly so, on the title-page, all promise so much, and yet—on looking beneath the surface we find no depth. Typical examples of the disappointments in store for the reader are furnished by Plates 14 and 15; it would be difficult to over-praise the beauty of the process-work of the former plate, and yet practically all the information the author gives is confined to a few meagre lines on pp. 58 and 60, chiefly concerned with a note as to where the specimen was found. True, more careful search shows that Plate 47 is concerned with the same subject, and somewhat more scientific hints are appended to this on p. 126; but why, in the name of all knowledge, are we not told something of the structure and development of these galls and their contents? Unless we are mistaken, or misled by synonymy, the very example here referred to is a classical one. Did not Dujardin describe the mite in the hazel-buds in 1851? and did not Miss Ormerod and Schlechtendal show that witches' brooms on the alder arise from the irritation set up by similar species? In this connection, also, excellent illustrations of the witches' brooms themselves are given on Plates 1, 16, 17 and 18, with such irritating gossip as "this very interesting tree stands just within the confines of the Park"—"Park," with a capital P!

Now, if we may be permitted to direct the attention of the author (who is the honorary general secretary to the Hastings and St. Leonard's Natural History Society) to the grand opportunity he has missed, pointing out at the same time that scientific experts rarely obtain the chance of putting forth their text illustrated in the superb style of this book, some service may be done in advocation of the cause of that most useful branch of biology —good descriptive field-work in the domain of the borderland between zoology and botany.

It is scarcely too much to say of the present book that if the text to these excellent plates had been nothing more than even a fair account of the insect and its gall, such as is given in a handbook like that of Frank, it would have been one of the most worthy and useful books on the subject—how much more so had the text risen to the level of Adler's admirable study of oak-galls! If local natural history societies would only resist the temptation to be popular, in the sense which implies being merely attractive to superficial and "smart" people, what an immense amount of valuable work might be done along the lines suggested by the present volume, which, disappointing though it is, is sufficiently good to show that the author must be capable of far better work.

We sincerely hope that in a second edition the author will give such notes concerning the structure and development of the galls, the habits of the insects producing them, and their effects on the plants infested by them, as could be obtained from such authors as we have quoted, and from the works of, for instance, Küster, Molliard and other modern investigators; such an account, added to the more extensive notes on field-work which Mr. Connold could evidently bring together—as may be judged from the present samples—should be worthy of the subject, and would be far more welcome to his fellow-lovers of nature than these pages of desert margin with their oases of meagre information, however excellent the latter may here and there be in itself. We are the more constrained to urge this because we understand that the author contemplates a separate book on oak-galls. If the illustrations are as good as these, and the text far better, we shall anxiously look for that book.

THE EVOLUTION OF LIFE.

L'Évolution de la Vie. Par le Dr. Laloy, Sous-Bibliothécaire de la Faculté de Médecine de Bordeaux. Pp. xii + 240. (Paris: Libraire C. Reinwald; Schleicher Frères, 1902.) Price fr. 2·50.

THIS volume is the third of a series being issued in France under the designation of the "Petite Encyclopédie du XX^e Siècle." The object of the work, as set forth in the preface, is the very praiseworthy one of spreading a sound knowledge of the achievements of modern science among the intelligent public in a popular way. As the author points out, the mental equipment of the man of culture of the present time consists of art, literature and *belles-lettres.* Of modern science he knows nothing and cares to know nothing. Even among scientific workers themselves the extreme specialisation necessitated by original work often prevents a general perspective of the whole subject being gained. The trees prevent the individual hewer of wood from seeing the forest as a whole. We have long recognised the need for imparting scientific "culture" to the reading and thinking public in this country, and many excellent series of popular works by our foremost men of science might be mentioned. How far the present work is likely to give French readers a sound idea of modern

evolution is very difficult for an English reviewer to judge. The author deals with the subject in a way that has been made familiar by the writings of Haeckel, and we cannot say that he sheds any new light on the various questions or that his treatment is particularly lucid. Here and there Dr. Laloy lets fall a suggestive analogy or makes a remark which shows that on many of the fundamental questions of modern biology his views are at any rate sound. If he admits of being pigeon-holed at all, we should say that as regards the origin of life he is a neo-vitalist. His suggestion that protoplasm may have arisen in the first place by the direct combination of carbon with water and the subsequent combination of the carbohydrate with nitrogen under the influence of the electric discharge (p. 28) is based upon a statement of Berthelot's—that cellulose and dextrin can "fix" nitrogen under the influence of the silent electric discharge. This view is not likely to find favour, we imagine, until we have some more substantial basis of fact to support it.

Concerning the descriptive part of the book, in which the various groups of animals and plants are dealt with from the point of view of evolution in ascending order, there is little to be said. The chief interest for the student of evolution is really concentrated in the seventh chapter, in which the author reveals his position. After putting forward the well-known arguments from rudimentary organs and embryology in favour of some doctrine of evolution being necessary, Dr. Laloy proceeds to consider the factors of evolution. He considers "la lutte pour la vie et la sélection" of Darwin to be inadequate and he accordingly assigns to natural selection a quite subordinate part in the formation of species. It is difficult, however, to find out precisely what is, according to the author, the prime factor of species formation. So far as can be gathered from the text, he appears to favour a kind of sudden and spontaneous variation of all the individuals simultaneously in the direction required to adapt them to new conditions (p. 104). He relies for this remarkable factor upon the experiments of Bonnier and the observations of De Vries, and he adds :—

"Ce serait selon moi cette variation brusque et totale, cet état de mutation, comme s'exprime De Vries, qui serait la véritable cause de la formation des espèces. La lutte pour la vie et la sélection ne seraient plus que des facteurs secondaires, qui n'entrent en jeu que pour fixer et rendre stables les variations acquises en bloc et surtout, pour supprimer les différenciations fâcheuses. Elles maintiennent les espèces dans leur caractère normal, mais ne sauraient en former de nouvelles. Ainsi, comme cause principale de l'évolution, nous retrouvons encore cette finalité du protoplasma qui lui permet de s'accommoder aux circonstances les plus diverses."

This is the key to the author's position as an evolutionist. It is not likely that many adherents to these views will be found in this country. Pure Lamarckism—however inadequate we may regard it—seems, on the whole, to have something more tangible about it than the variation "brusque et totale" of all the individuals of a species in order to meet any emergency in the conditions of life. It is remarkable that a countryman of Lamarck's should go out of his way in order to introduce a factor which receives such very slender support from the observed facts of nature.

R. M.

OUTLINES OF PHYSIOLOGY.

A Primer of Physiology. By Alec Hill, author of "An Introduction to Science," &c. Pp. x + 105. (London : J. M. Dent and Co.)

IN this tiny primer of 105 pages the author attempts to give a general sketch of the subject of physiology, treating especially of those parts which may be supposed to be of most interest to a reader who is not contemplating the profession of medicine, and has not the appliances of a laboratory at his command.

As the author truly remarks in his preface :—

"The subject is so vast that a series of primers would be needed to approach its several departments through the elements of physics, chemistry, anatomy, and the other sciences upon which they are based."

Mr. Hill does not state whether these needed primers are subsequently to appear from his pen, but should they do so there is little doubt that they will prove quite as interesting to the student of physiology as the one now under consideration.

Although the space at his disposal is so exceedingly limited, yet the author finds room to dip occasionally into the realms of medicine. Here is an example of such an application taken from p. 14 :—

"The expression to 'purify the blood' is a vestige of a long-abandoned theory of medicine. In the sense in which it is used, to imply that carbuncles, boils and pimples are due to 'bad blood,' it is absurd and misleading. It is none the less true, however, that health, as shown by muscular vigour and perfect freedom from neck-ache, pains in the limbs, and other 'gouty' symptoms depends upon the blood being fully charged with oxygen, and sufficiently free from nitrogenous waste products to keep the juices of the body in a pure state."

Then in a few cogent words the author deals with the *rationale* of massage, the effect of hot baths, and the therapy of diuretics such as "sweet spirits of nitre" or "salts of various kinds"; and all this is done in one short half page.

Terseness is naturally the characteristic of this little primer throughout, but we scarcely agree with the tacitly assumed idea of the author that by the judicious use of leaded type the necessity for wasting precious space in giving definitions can be avoided. For example, the hitherto uninstructed person in physiological matters will scarcely understand at a first glance what is meant by lymph, epithelium and protoplasm, unless some explanation, other than that mentioned above, be given him.

The book opens with a four-page account of the structure, given necessarily in hasty outline, of the mammalian body; there follow eight or nine pages on minute anatomy, in which half a page is found for a description of "caryokinesis," and then, in less than forty pages, the blood and vascular system, the neuro-muscular system, digestion, absorption, dietetics and respiration are rapidly reviewed. Rather more than half the space is thus left over for the central nervous system and special senses, and here in his own special domain the author is peculiarly at home, and his imageries and analogies are at

times perfectly delightful. Take, for example, the analogy given to illustrate the perception of sensation on p. 61:—

"An errand boy pulls a bell handle (he stimulates a sense organ); the pull is conveyed up the wire (an impulse travels to the central organ); the bell rings (a sensation is produced); the maid-servant hears the bell (the sensation is perceived); she decides that a person has pulled the bell handle (passes a sensory judgment). Perhaps she is able to infer, from the violence of the ring, that it was a telegraph boy who pulled the handle. Probably she goes to the door and opens it—this is equivalent to translating sensation into action with the acquiescence of consciousness."

There is a touch of genuine humour, perhaps unconsciously given, in the use of the word "probably" in the concluding sentence of this fine description.

Finally, it may be said that few will read Mr. Hill's little primer, with its great wealth of popular allusions and applications, without learning something new, even if they be trained physiologists, although it is somewhat doubtful whether the book is not a little too condensed for a beginner.

The illustrations, like the ext, are original, and are in every respect worthy of it. Attention may here be drawn especially to the great simplicity of the diagrams of a sphygmograph on p. 20 and of the pendulum myograph on p. 33.

B. MOORE.

A PROTEST AGAINST VITALISM.

Mechanismus und Vitalismus. By O. Bütschli. Pp. 107. (Leipzig: W. Engelmann, 1901.) Price 1*s*. 9*d*.

THE work before us is a reprint of an address delivered before the International Congress of Zoology at Berlin in 1901, amplified by the addition of a preface and of explanatory and supplementary notes, which exceed considerably in bulk the original lecture. The author takes as his theme the most fundamental problem of biology, namely, the relation of life and living things to the inorganic world. With regard to this question, biologists fall, consciously or unconsciously, into two camps—on the one hand the vitalists, who do not believe that an ultimate explanation of the phenomena of life can be given in terms of the not-living; on the other hand, the "mechanists," as they are here named, who "consider it possible, even though feasible only to the most limited extent at the present time, to comprehend vital forms and vital phenomena on the basis of complicated physico-chemical conditions" (p. 8).

Prof. Bütschli, whose researches on the structure and properties of protoplasm have brought him into the closest contact with the problem of the nature of living matter in its simplest and most elementary form, approaches the question as a partisan of the mechanistic school of thought, and seeks to vindicate this position against the recent revival of vitalism which has been so prominent of late years, especially amongst physiologists. He commences with a brief exposition of his philosophical standpoint, and expresses himself "of the opinion that sensations (Empfindungen) accompany the processes (Vorgänge) of the entire world, but that consciousness, or conscious sensation, on the other hand, has come about through the building up of the nervous system, and consequently of memory, which is the foundation and cornerstone of the conscious object, or of the Ego" (p. 6 Memory is not to be regarded as a property of the livir substance as such, but as possible only with a complicat nervous apparatus (p. 52). The author proceeds next define the mechanistic position and especially to d tinguish "Mechanismus" from Materialism, with whi it has been confounded by Bunge and other vitalis "The mechanistic conception does not imply that psychical can be explained by the physical; to it these t fields appear separate, though not unconnected" (p. This leads to brief discussions as to what is meant b "causal dependence," and as to how far it is possible to speak of an "explanation" of natural phenomena, after which the author passes on to review and criticise the objections raised by neo-vitalists to the possibility of explaining vital phenomena from a physicochemical standpoint.

It is not possible here to follow the author into the details of his arguments upon this abstruse theme for which we must refer the reader to the original Suffice it to say that the lecture makes interesting reading but by no means of a light order, since almost ever sentence requires to be pondered over before it can b assimilated, and we imagine that the inevitable butterfly element amongst the professor's audience must have found it difficult to gather honey from such very solid mental food. Perhaps the difference between the mechanists and the vitalists is nowhere brought out better than on p. 17. A neo-vitalist, Cossmann, having asserted that an artificially manufactured body, of the same materia and of the same structure as a plant, would neverthele not be an organism, Bütschli replies that "a bod built up in exactly the same way, both as regards stru ture and material, as a given plant, cannot, under suitab external conditions, behave otherwise than would the plant in question, *i.e.*, it would live like it." So long this ideal artificial organism has not been put togeth it seems a little difficult for an unbiassed critic (if the be any such) to assert confidently, either with t mechanist, that it would behave as a living body, or wit the vitalist, that it would be in the condition of a dea one. Incidentally, Bütschli declares his belief that t Darwinian theory of evolution, in spite of the many rece attacks upon it, remains the most probable of the vari attempts at explanation, and "contains the possib general solution of the problem," especially if combin with the hypothesis of germinal variations, which alo are capable of being inherited (pp. 33 and 89). In con clusion, the author claims that, in vital phenomena, "only that can be comprehended which can be physico-chemically explained." As regards the merits of the vitalistic and mechanistic points of view, he is content d clare, "By their fruits shall ye know them!"
